Lecture 05
Color and Perception

Sept. 3, 2015

Agenda

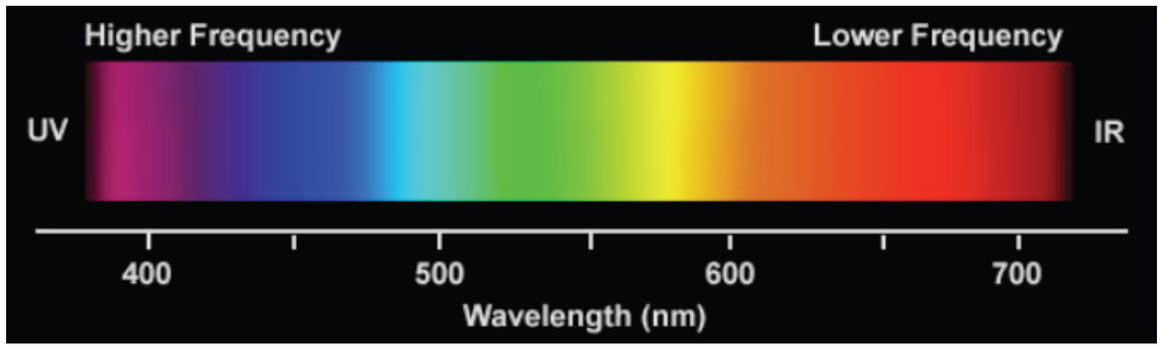
- PA01 questions?

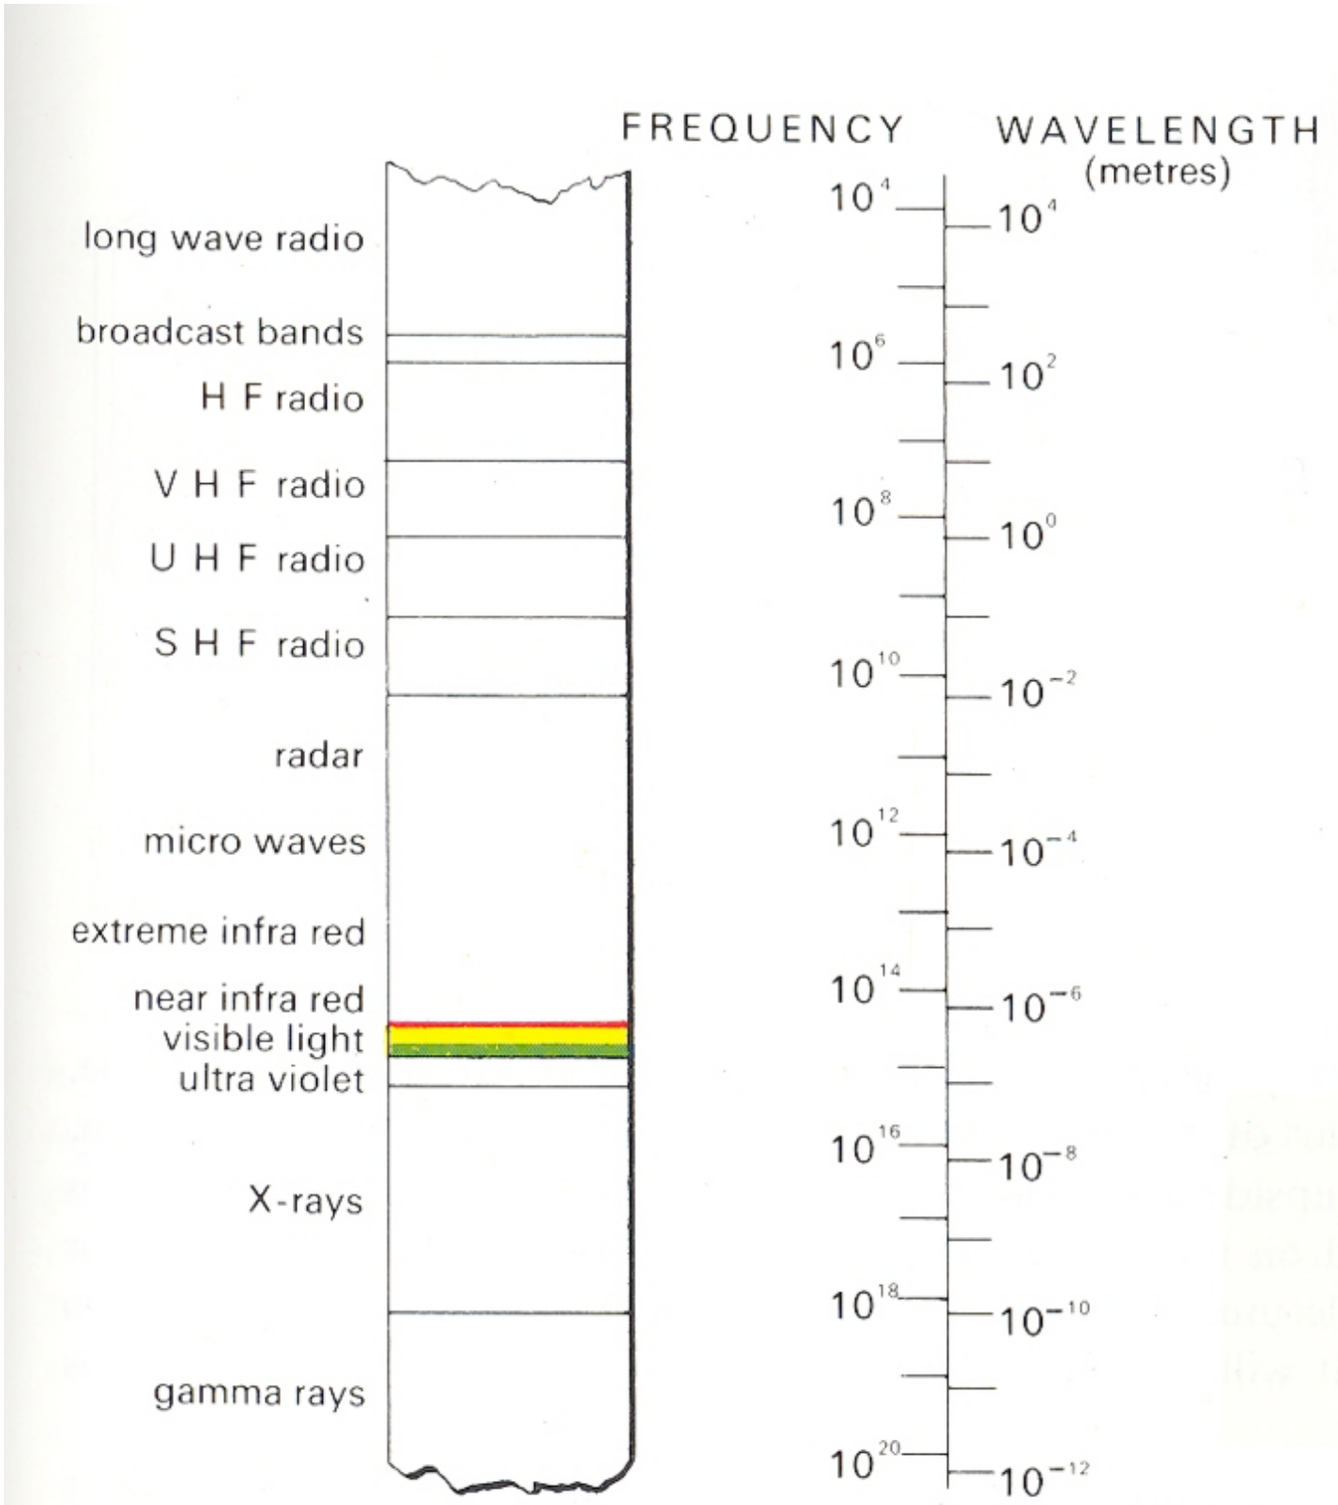
- Quiz01 POSTED, due Thurs., Sept. 10 at start of class

From Last Time…

Light is Electromagnetic Radiation

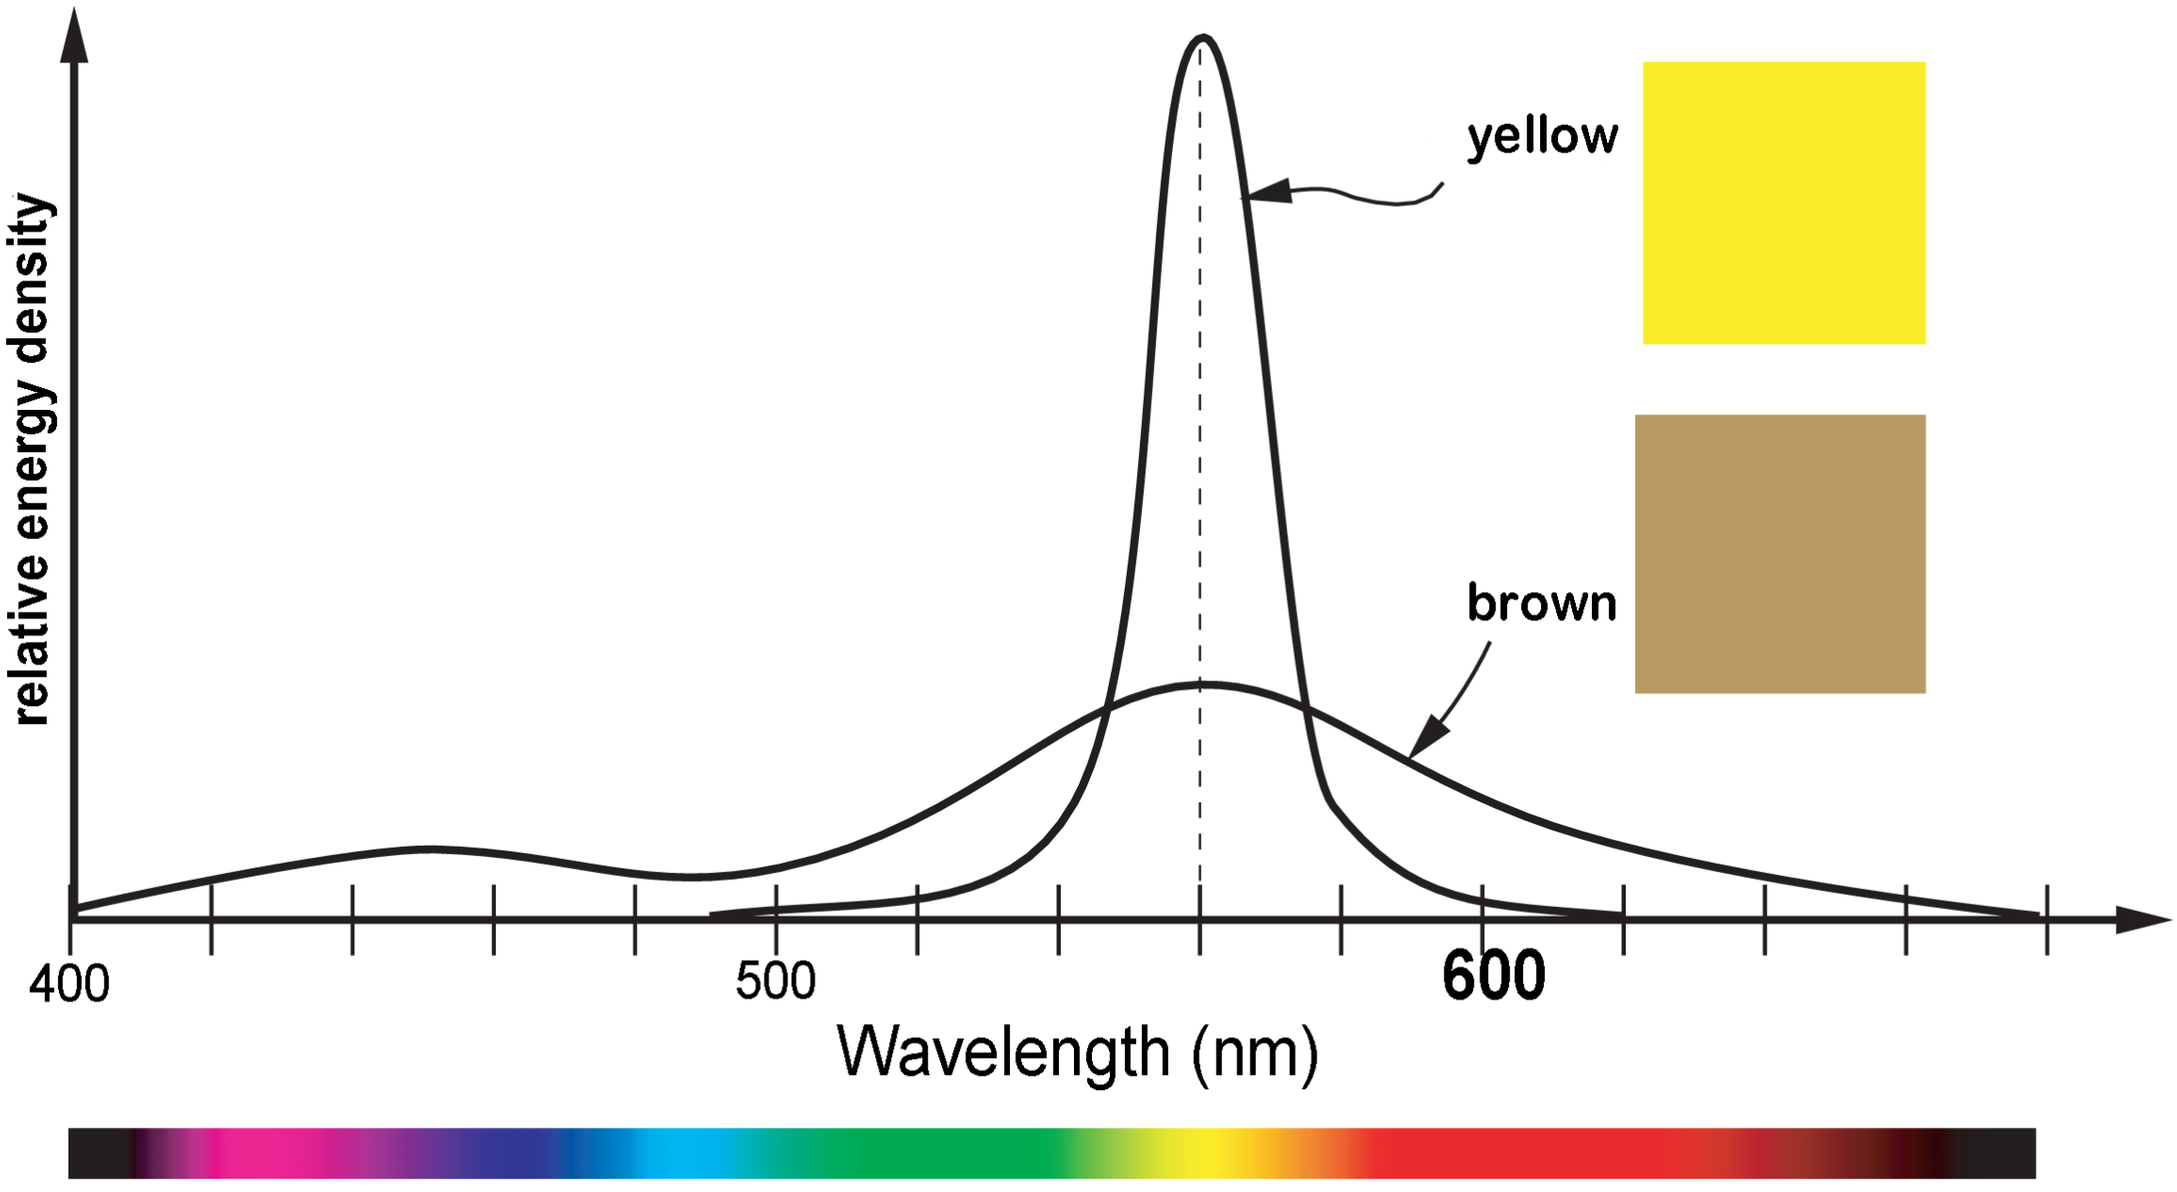
- Visible spectrum is “tiny”
- Wavelength range: 380-740 nm





Color != Wavelength

But rather, a combination of wavelengths and energy



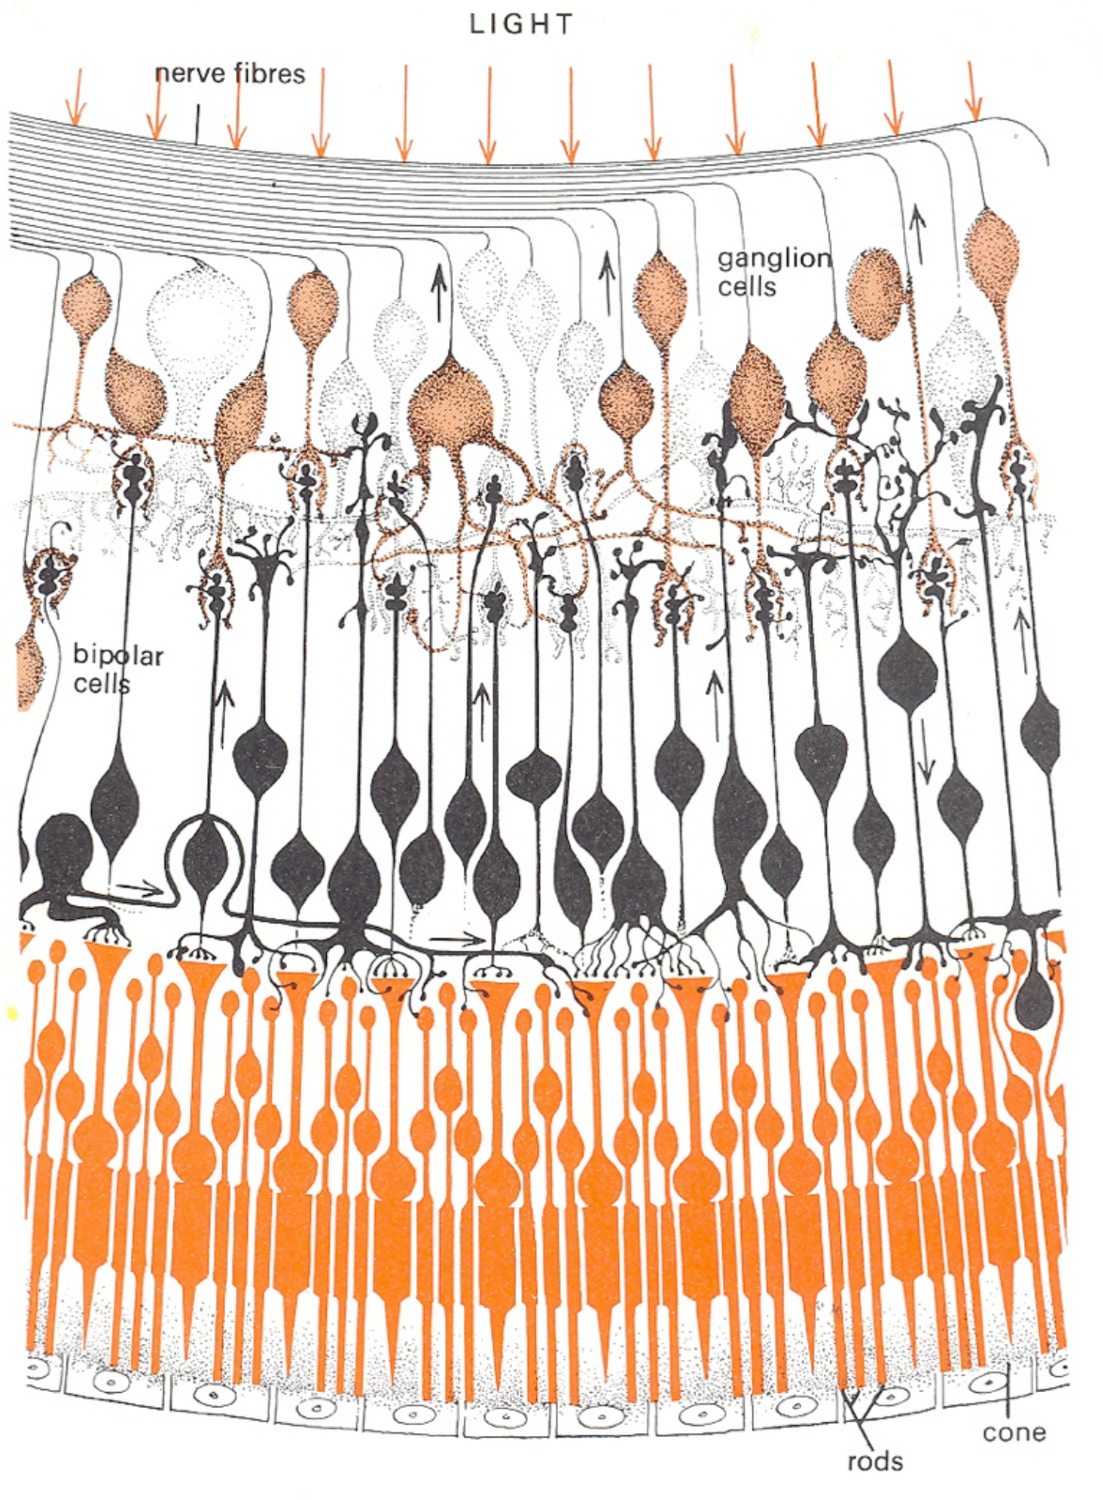
Photoreceptors

Rods

- Approximately 100-150 million rods.
- Non-uniform distribution across the retina
- Sensitive to low-light levels (scotopic vision)

Cones

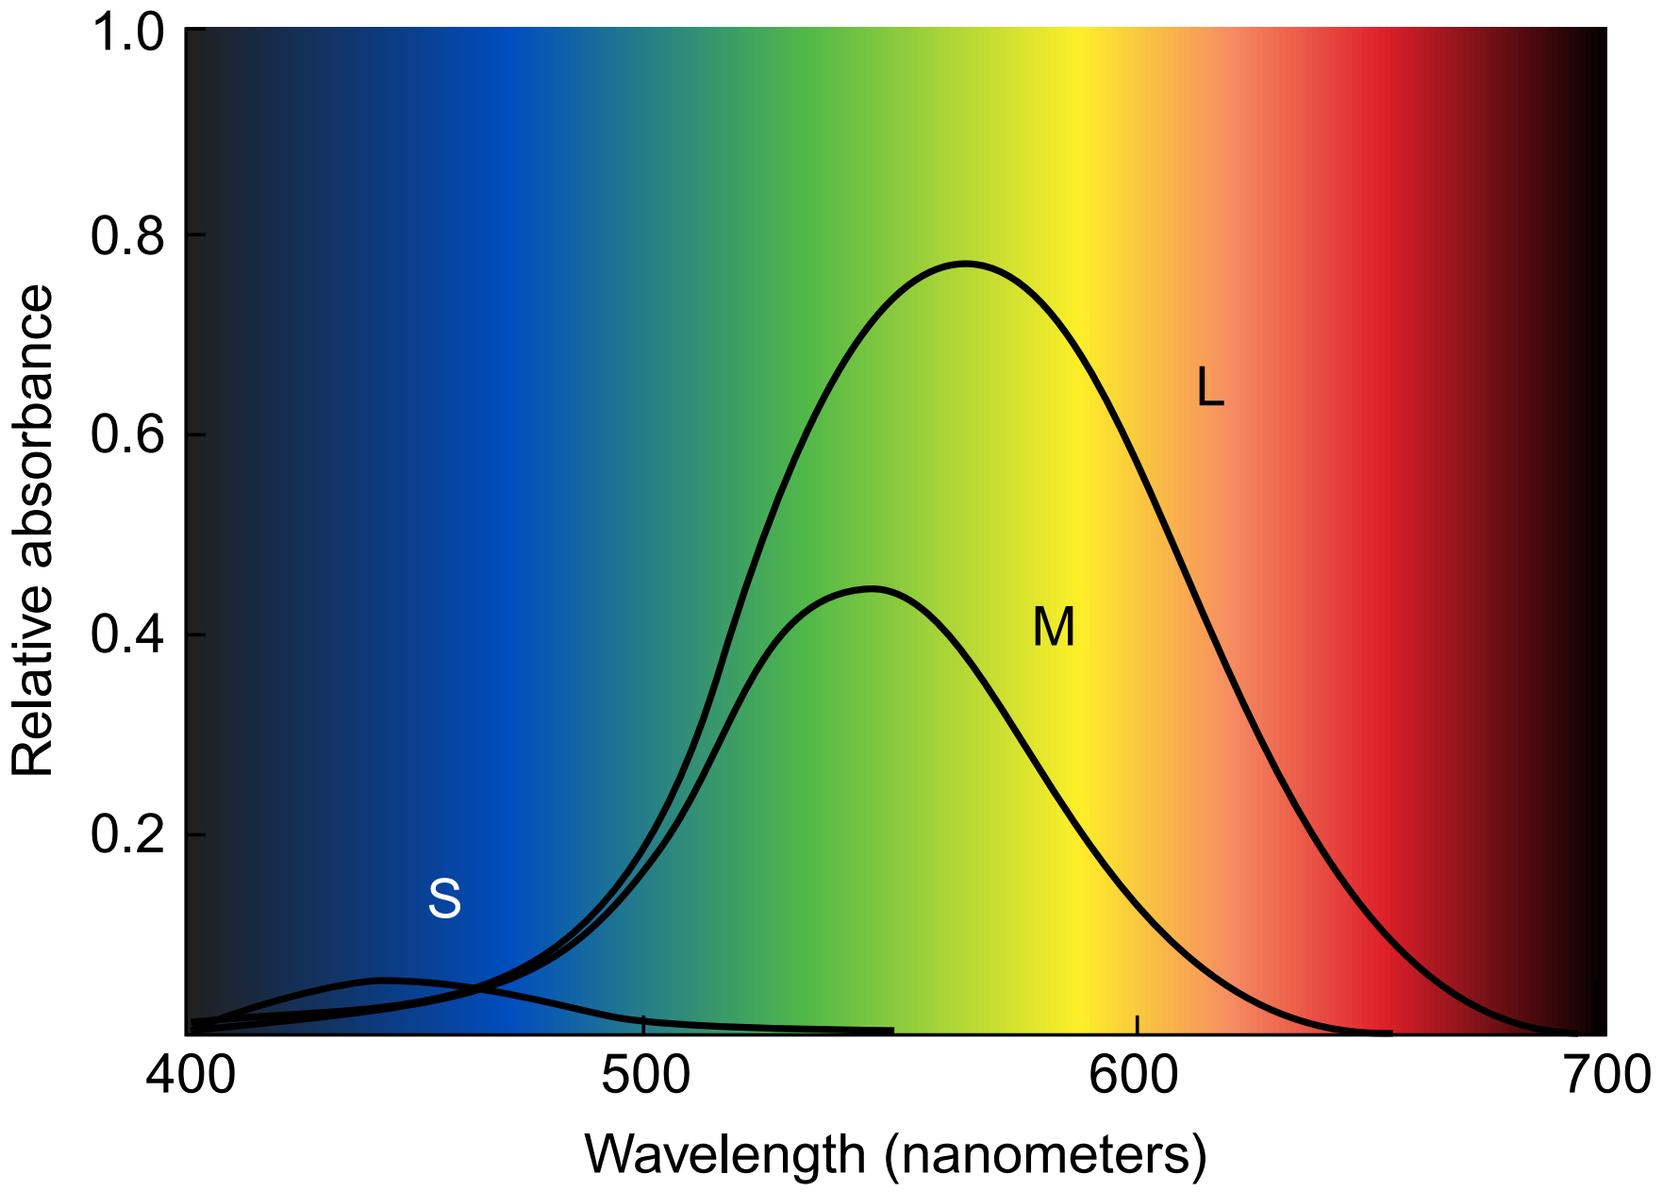
- Approximately 6-7 million cones.
- Sensitive to daytime-light levels (photopic vision)
- Detect color by the use of 3 different kinds:
  - Red (L cone) : 564-580nm wavelengths (65% of all cones)
  - Green (M cone) : 534-545nm (30% of all cones)
  - Blue (S cone) : 420-440nm (5% of all cones)



Color and Perception

Cones (SML)

(short, medium, long)



Colin Ware, Information Visualization: Perception for Design

Hunters

Gatherers

Trichromacy

- Our 3 cones cover the visible spectrum
  - Theoretically, all we need are 2 though
- Most birds, some fish, reptiles, and insects have 4, some as many as 12 (Mantis Shrimp)
- This is a “reason” why many of our color spaces are 3D

Mantis Shrimp

16 Photoreceptors, 12 for color sensitivity!

Idea: Perception of Color

Ultimately, color is a perceptual phenomenon, we all see it differently

Color Models

Terminology

- **Color Model**
  - Is an abstract mathematical system for representing color.
  - Is often 3-dimensional, but not necessarily.
  - Is typically limited in the range of colors they can represent and hence often can’t represent all colors in the visible spectrum

- **Gamut** or **Color Space**
  - The range of colors that are covered by a color model.

Calvin and Hobbes

by Watterson

What are the primary colors?

1. Red, Green, Blue
2. Red, Yellow, Blue
3. Orange, Green, Violet
4. Cyan, Magenta, Yellow

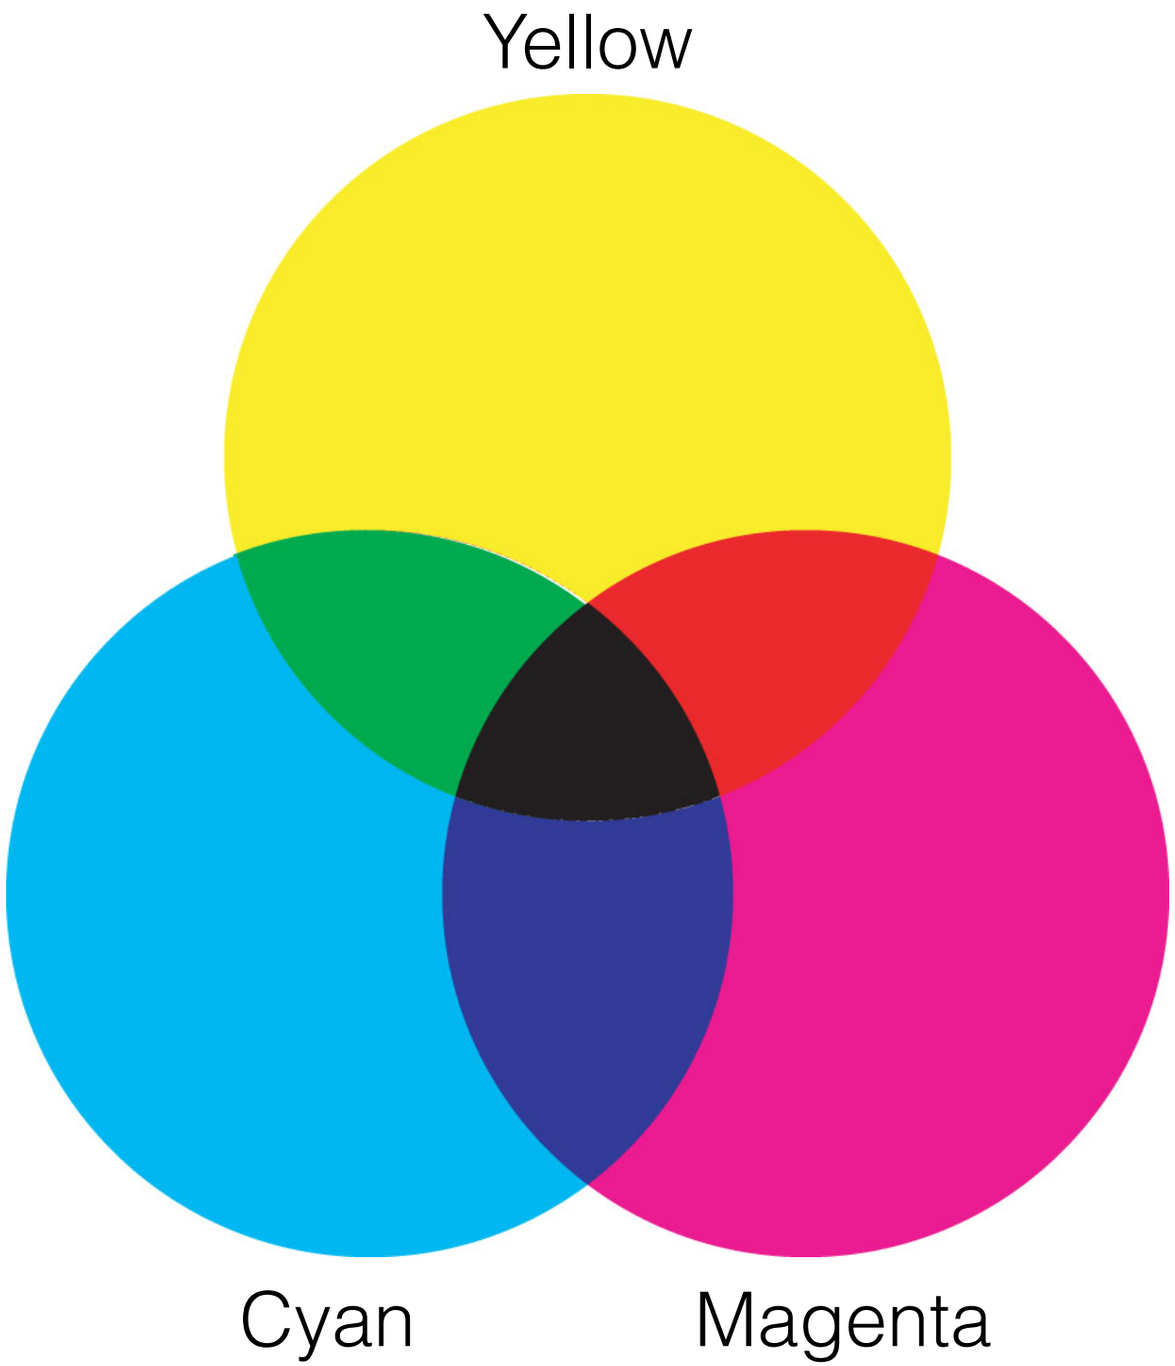
What are the primary colors?

1. Red, Green, Blue
2. Red, Yellow, Blue
3. Orange, Green, Violet
4. Cyan, Magenta, Yellow
5. All of the above

Light Mixing

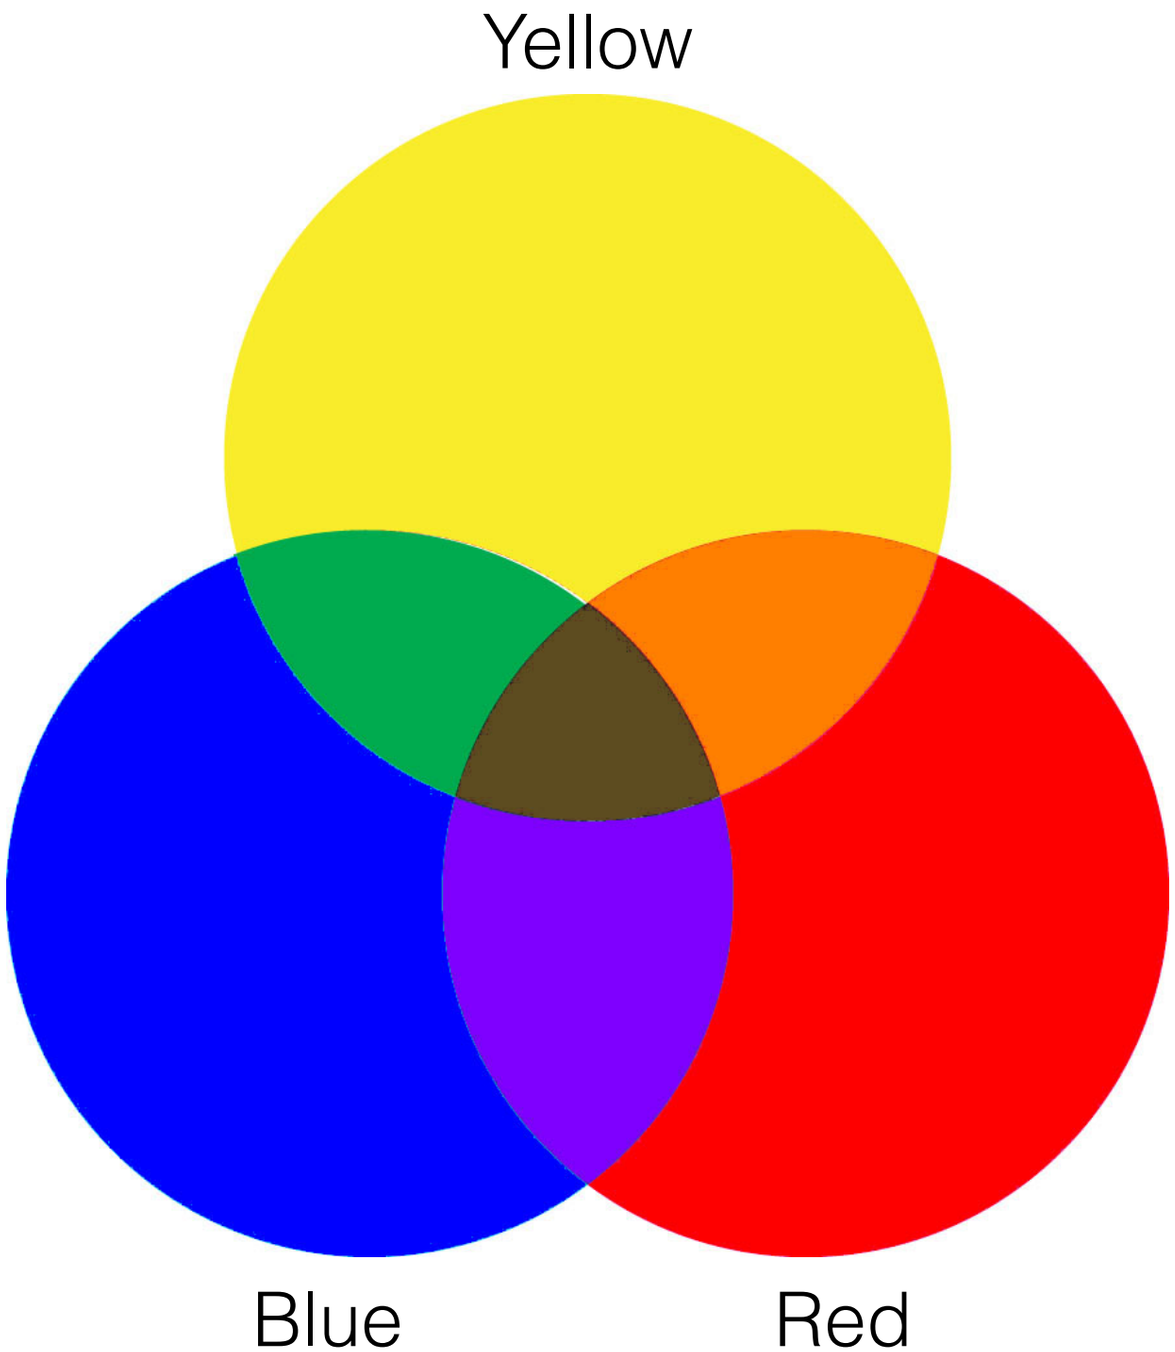
- **Additive** mix of colored lights
  - Add up wavelengths of light to make new colors
- Primary: RGB
- Secondary: CMY
- Neutral = R + G + B
- Commonly used by monitors, projectors, etc.

Ink Mixing



- **Subtractive** mix of transparent inks
  - Start with white and other wavelengths are selectively filtered.
- Primary: CMY
- Secondary: RGB
- ~Black: C + M + Y
- Actually use CMYK to get true black

Paint Mixing

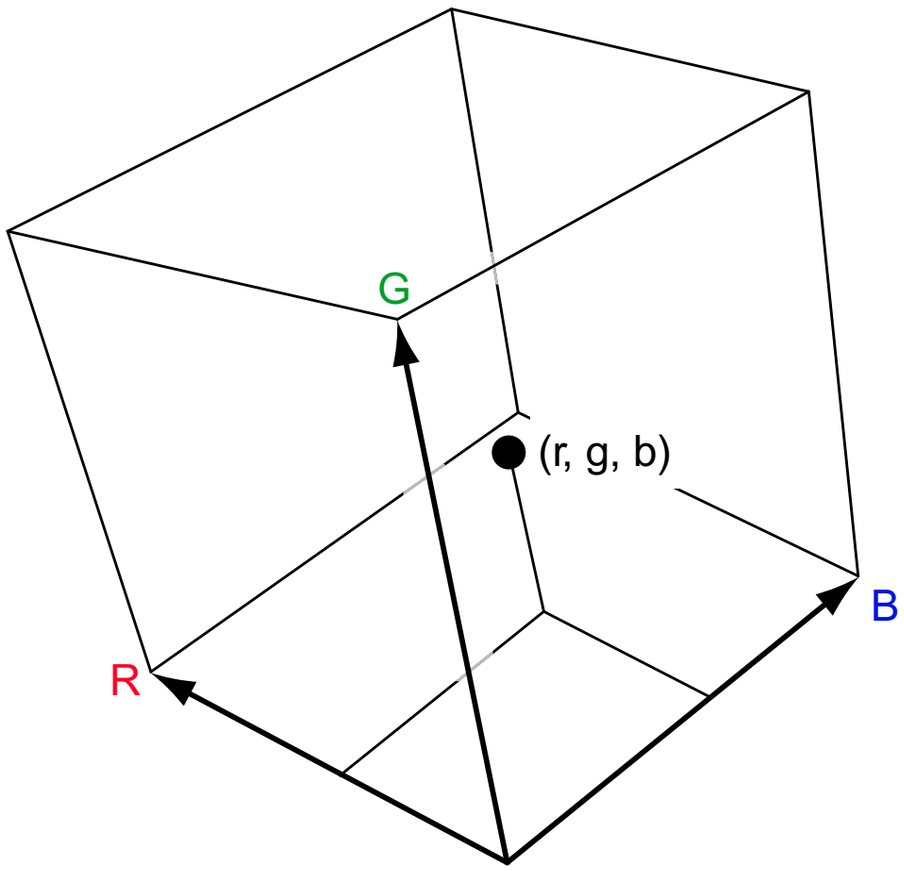


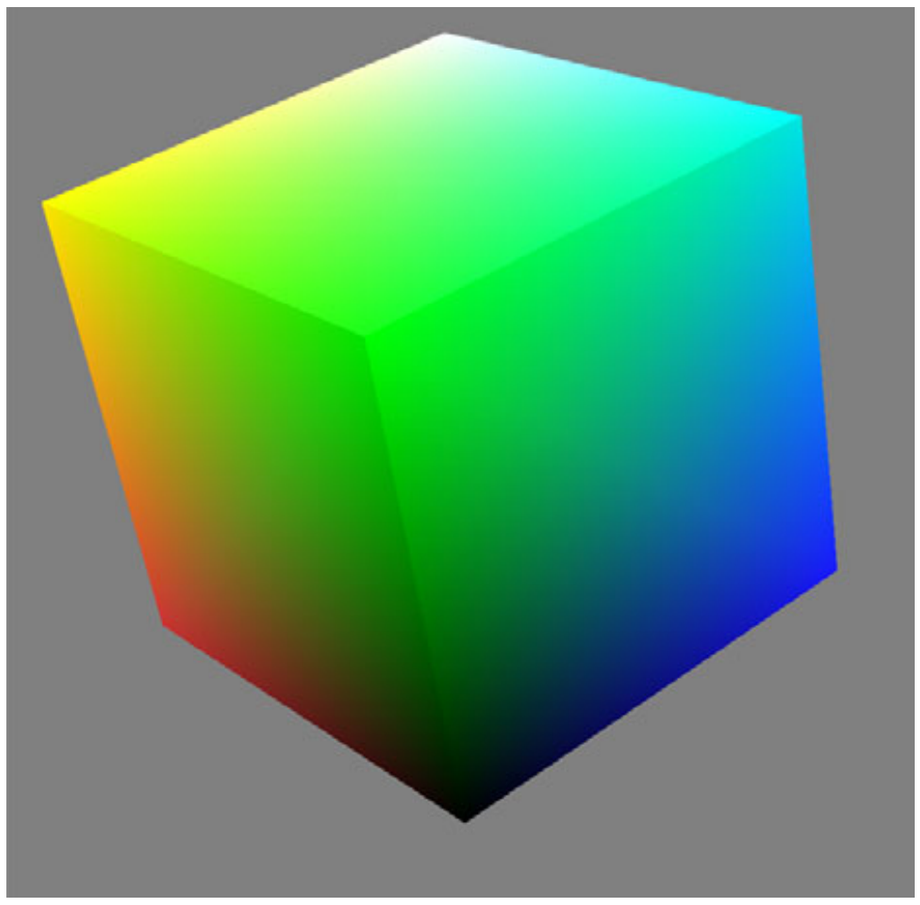
- Physical mix of opaque paints
- Primary: RYB
- Secondary: OGV
- Neutral: R + Y + B
- Additive or Subtractive?

Color Spaces

RGB Color Space

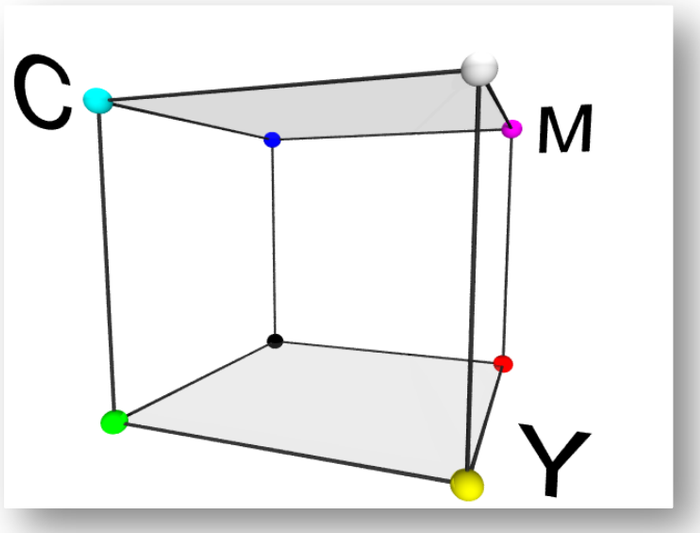
- Additive, useful for computer monitors
- Not perceptually uniform
  - For example, more “greens” than “yellows”



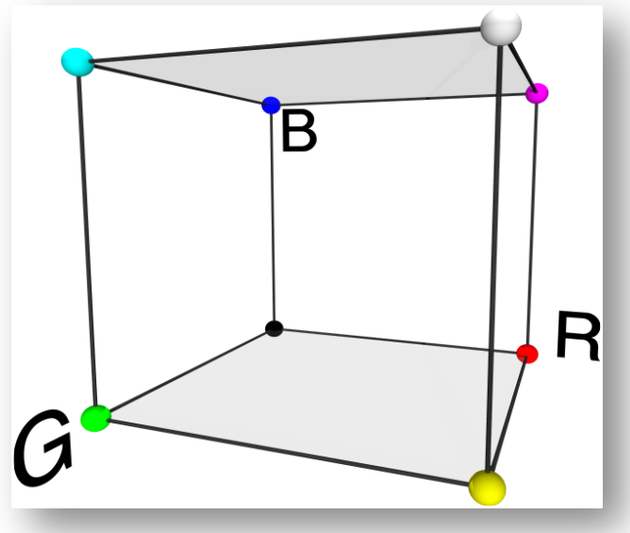


Converting from RGB to CMY

- Assuming RGB values are normalized (all channels between [0,1]), the exact same color in CMY space can be found by inverting:



$$\begin{bmatrix} C \\ M \\ Y \end{bmatrix} = \begin{bmatrix} 1-R \\ 1-G \\ 1-B \end{bmatrix}$$



Converting from CMY to CMYK

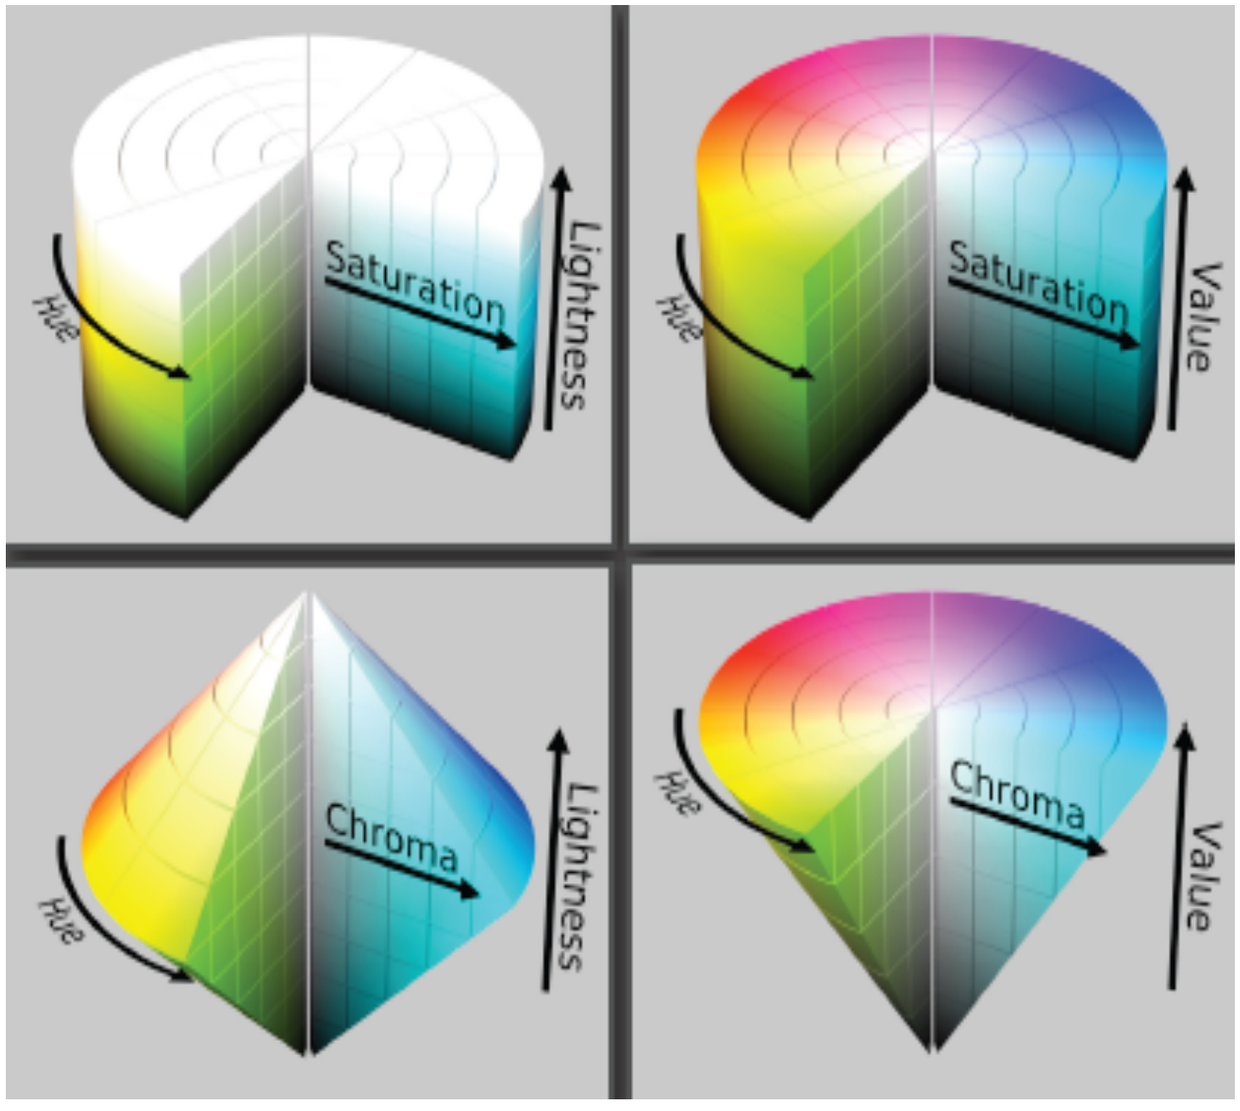
- Assuming CMY values are normalized (all channels between [0,1]), the exact same color in CMYK is

$$\langle C, M, Y, K\rangle = \begin{cases} \langle 0, 0, 0, 1\rangle & \text{if } \min(C', M', Y') = 1, \\ \langle \frac{C'-K}{1-K}, \frac{M'-K}{1-K}, \frac{Y'-K}{1-K}, K\rangle & \text{otherwise where } K = \min(C', M', Y') \end{cases} \quad (3.2)$$

- K is a measure of the ‘blackness’ of the color and essentially serves as an offset after which the remaining amounts of cyan, magenta and yellow are ‘added’

(H,C/S,L/B/V) Color Space

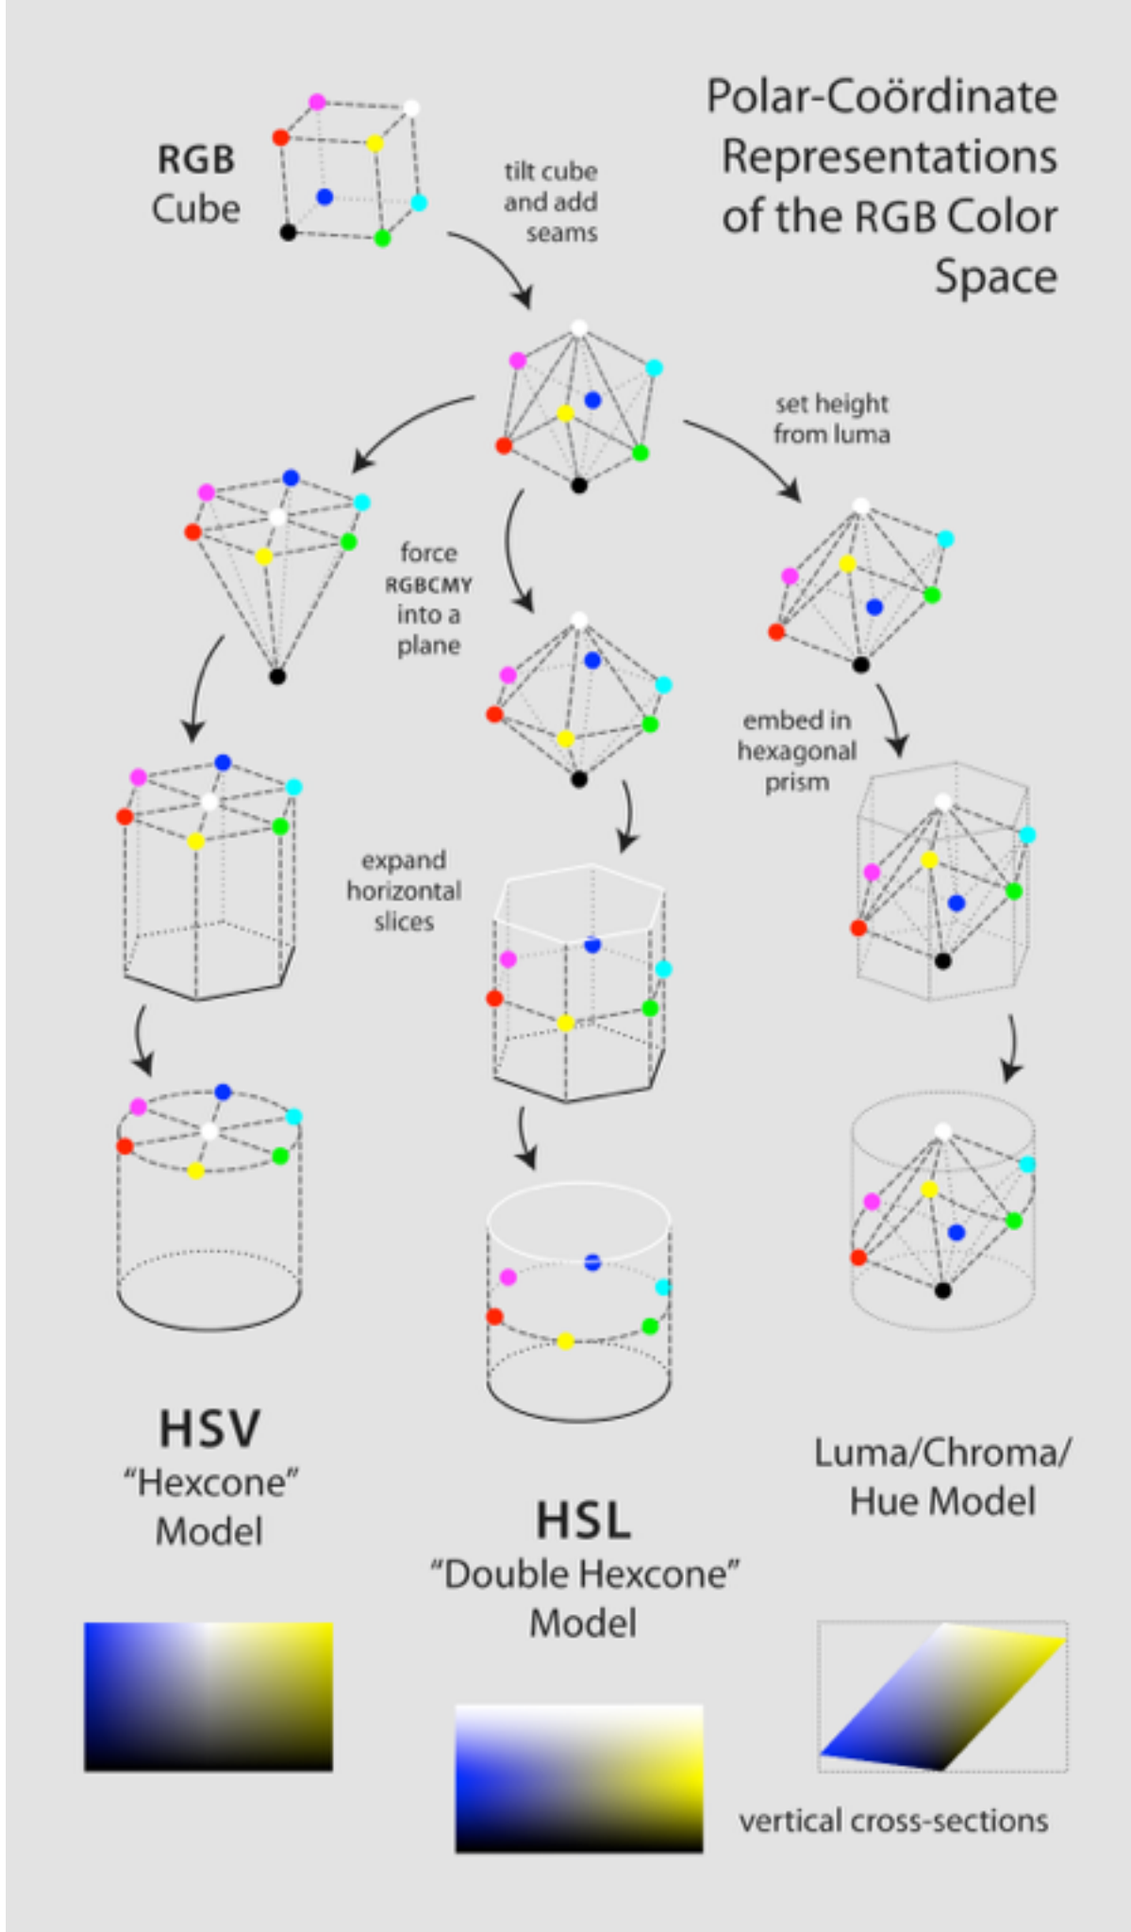
- Hue - what people think of as color
- Saturation - purity, distance from grey
    - Also called Chroma
- Lightness - from dark to light
    - Also Brightness or Value



HSV by Projection of RGB

- This decomposition is more natural for how we sense color, decomposes brightness component from color.
- More natural for artists, regardless of which variant
- Note that H is cyclical
  - H=0 is the same as H=1.

http://en.wikipedia.org/wiki/HSV_color_space



Conversion from RGB to HSB

- Assuming RGB values are normalized (all channels between [0,1]), the exact same color in HSB space can be found by first figuring out which channel (R,G, or B) has the max intensity

$$
H = \begin{cases} \text{undefined} & \text{if } \max = \min, \\ 60 \times \frac{G-B}{\max - \min} & \text{if } \max = R \text{ and } G \geq B, \\ 60 \times \frac{G-B}{\max - \min} + 360 & \text{if } \max = R \text{ and } G < B, \\ 60 \times \frac{B-R}{\max - \min} + 120 & \text{if } \max = G, \\ 60 \times \frac{R-G}{\max - \min} + 240 & \text{if } \max = B. \end{cases} \tag{3.3}
$$

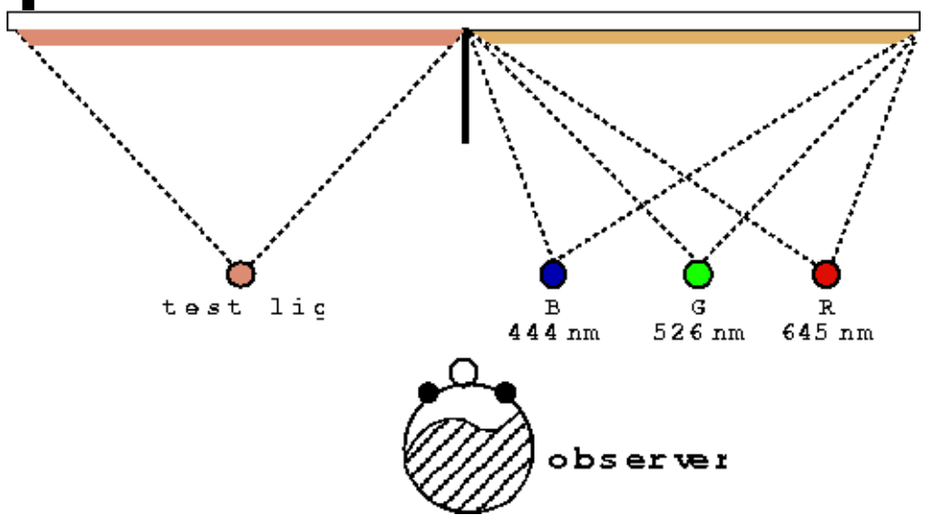
$$
S = \begin{cases} 0 & \text{if } \max = 0, \\ 1 - \frac{\min}{\max} & \text{otherwise} \end{cases}
$$

$$
B = \max .
$$

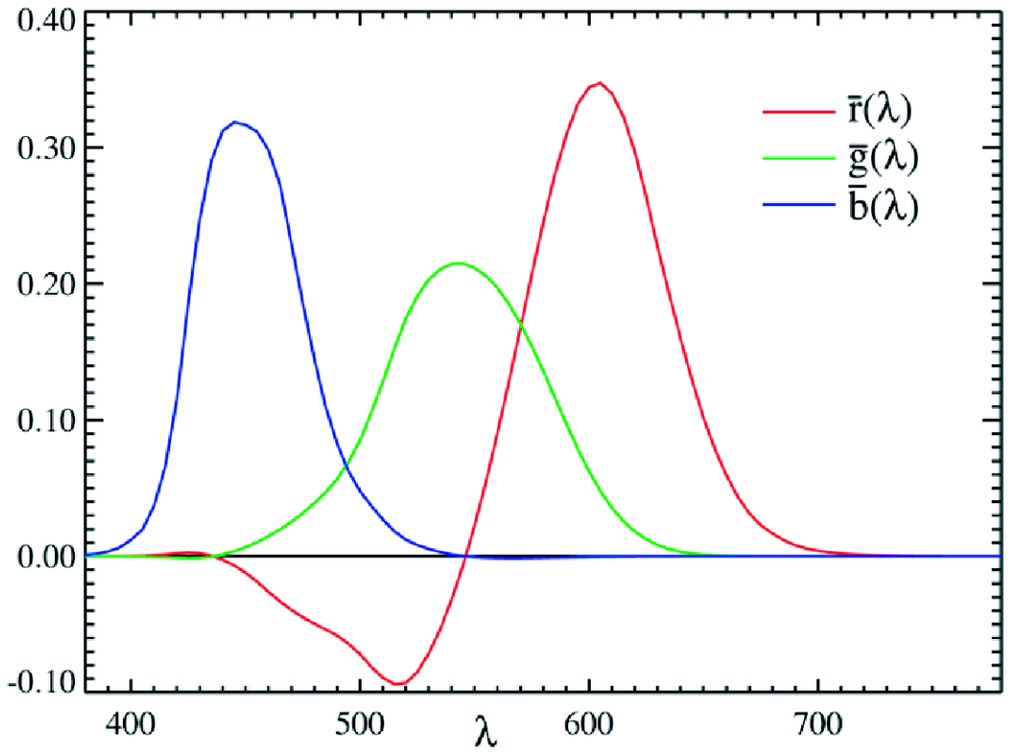
Note: returns H as a value between 0° and 360°

Tristimulus Experiment

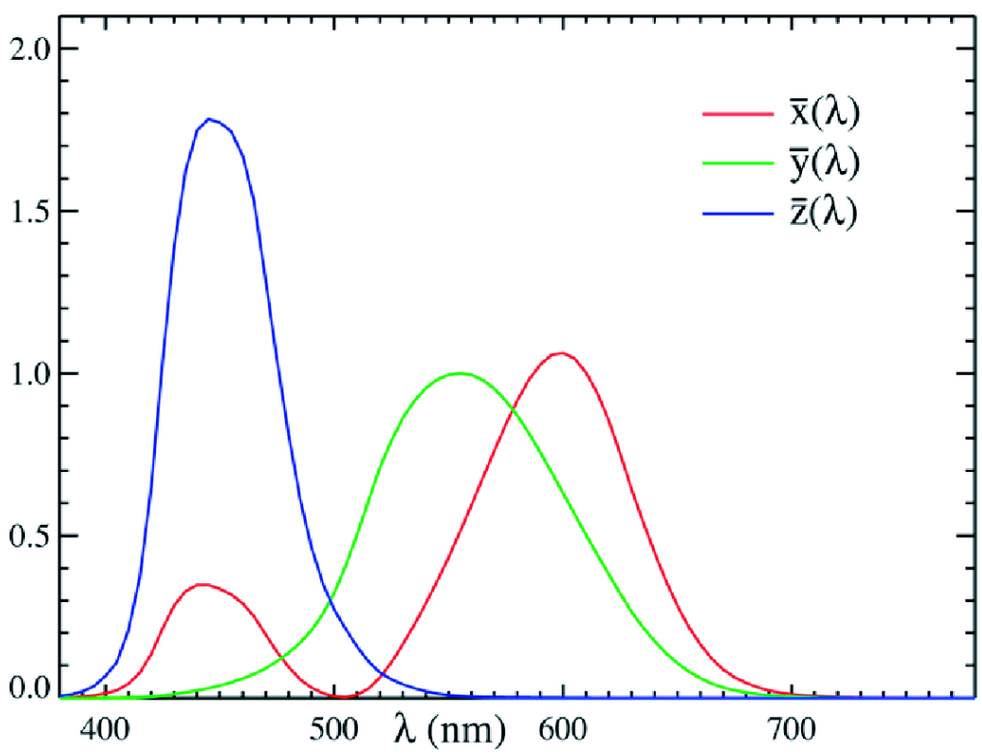
- Color Matching Experiment in 1931
- CIE = International Commission on Illumination (Commission internationale de l'éclairage)
- Since some weighting factors for R,G,B lights are negative, they computed a new set of weights for a new of components X,Y,Z



RGB Weights



XYZ Weights



Converting from CIE XYZ to xyY

- To build a system which separates luminance (Y) from chromaticity (xy) we can do an operation similar to converting CMY to CMYK:

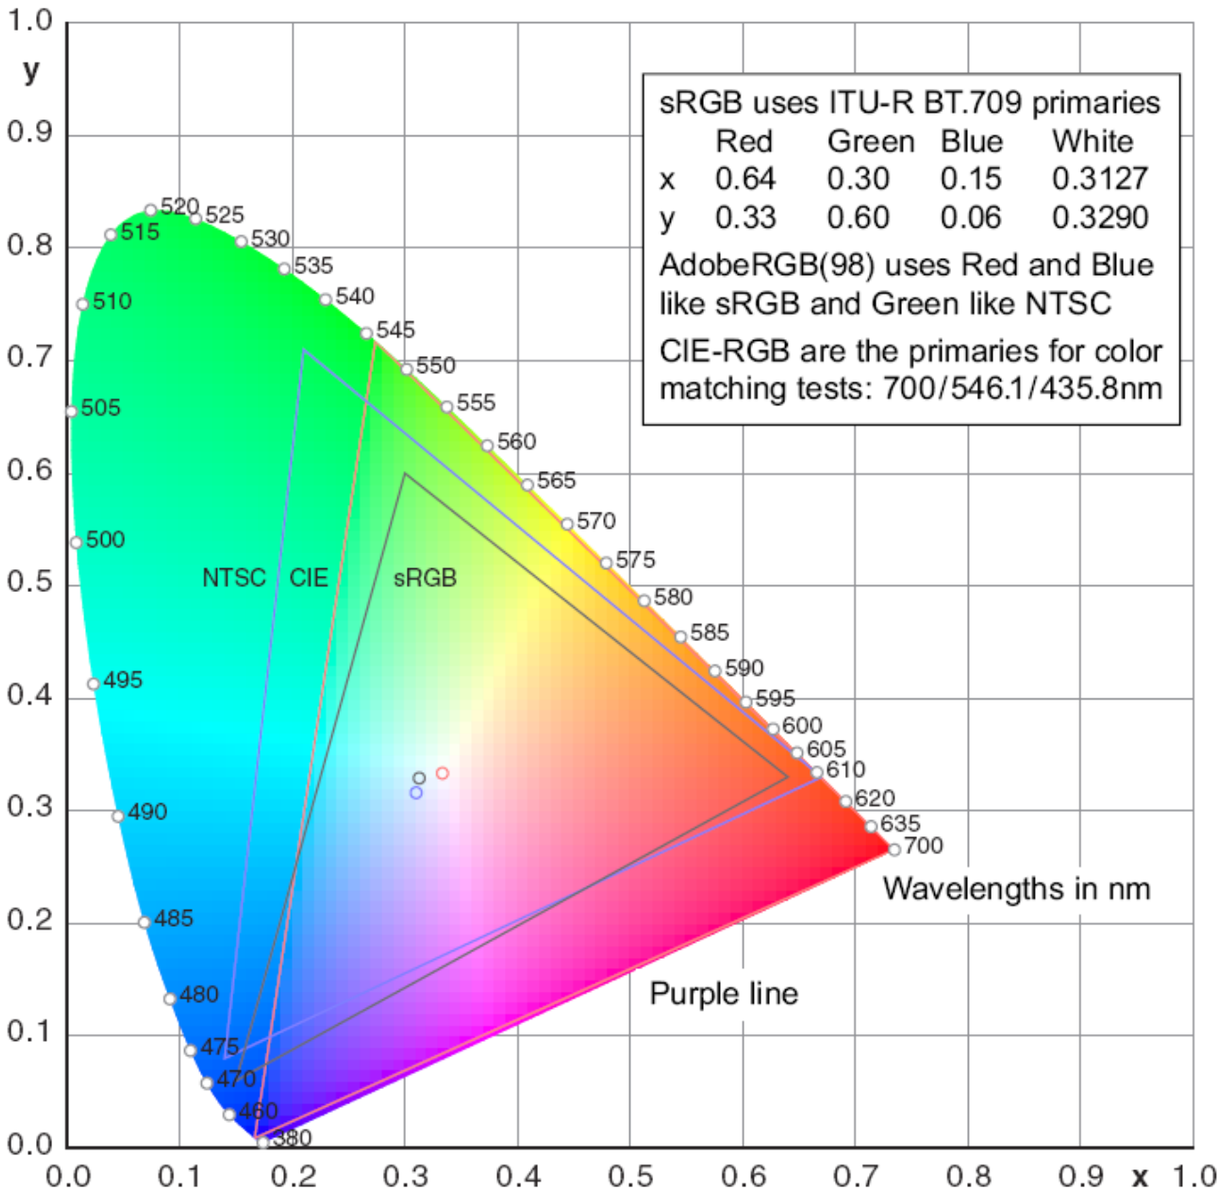
$$x = X / (X + Y + Z)$$

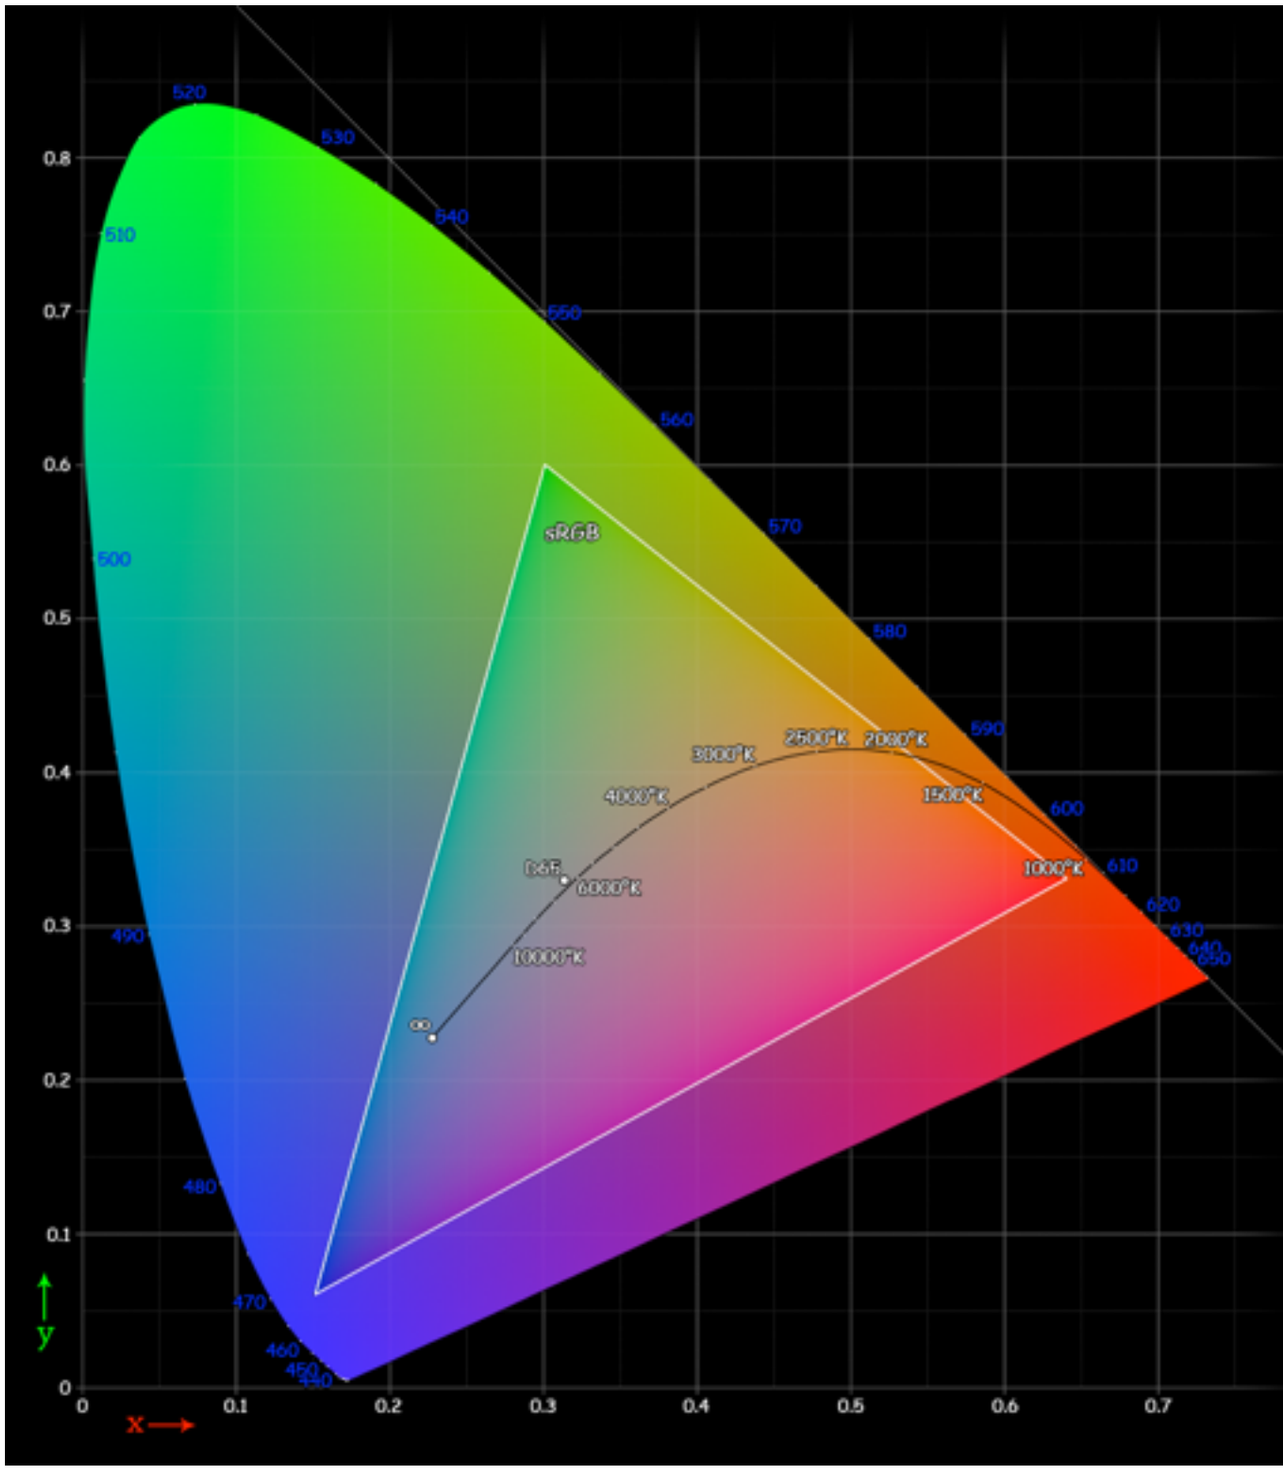
$$y = Y / (X + Y + Z)$$

$$Y = \text{luminance}$$

CIE Space

Note: Colors outside the triangle cannot be accurately displayed



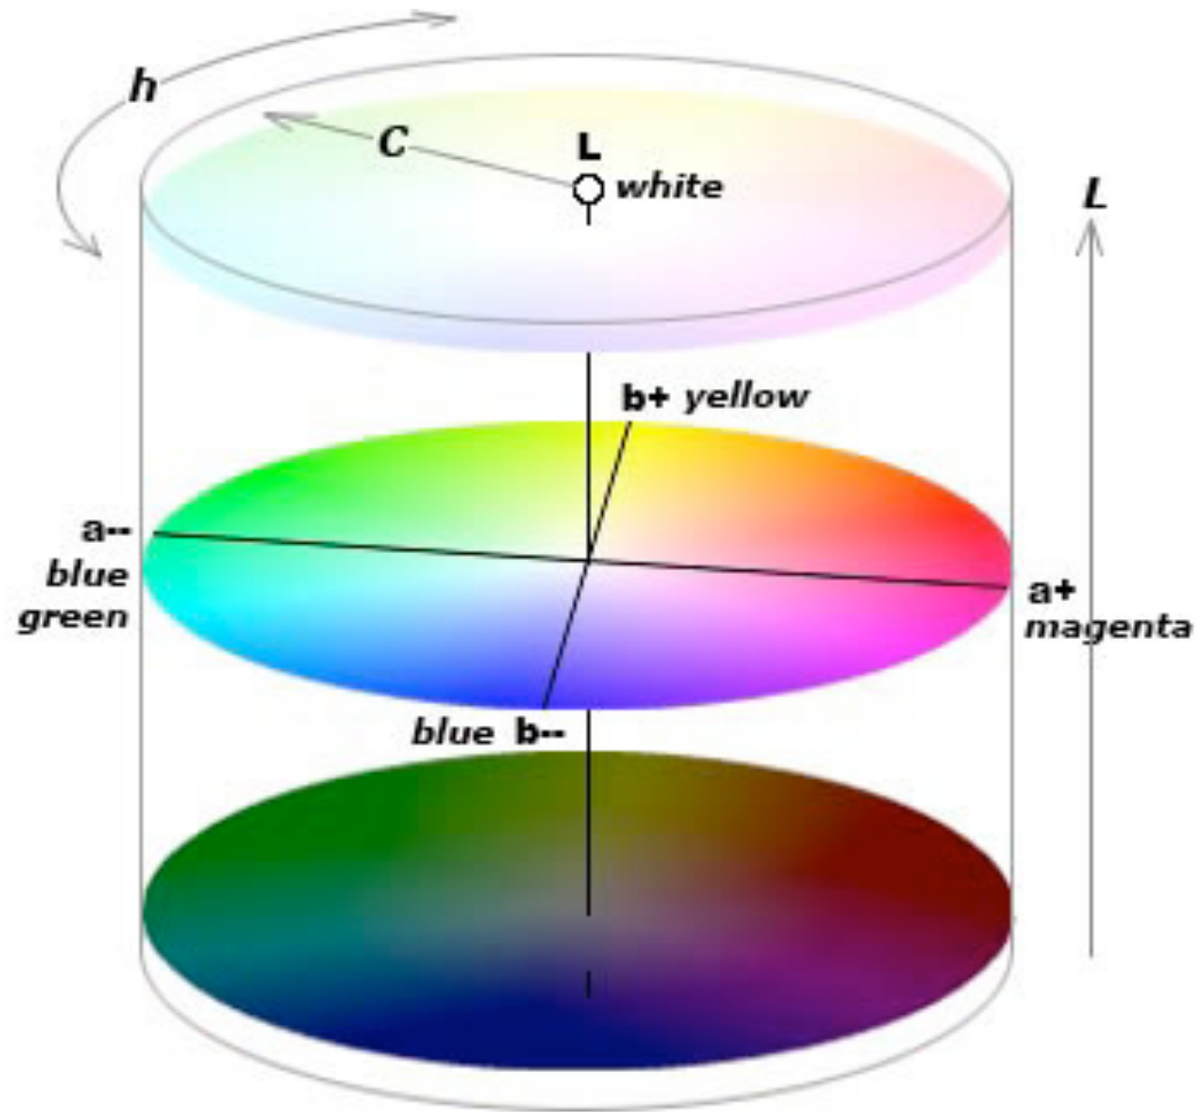


CIELab/Luv

- Perceptual uniform transformation of XYZ

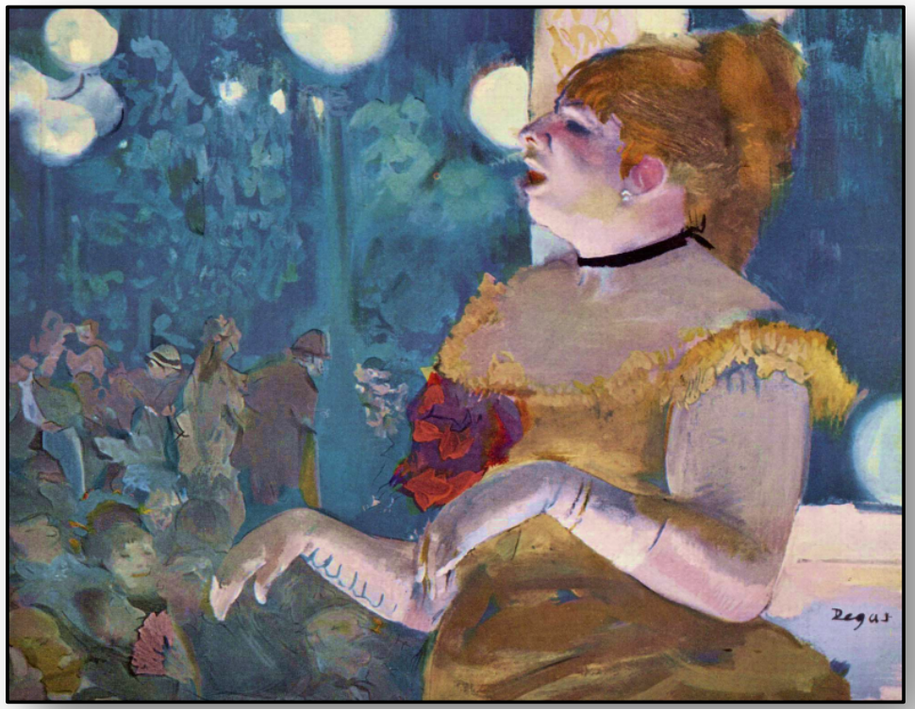
- L approximates luminance or Y in XYZ

- (a,b) & (u,v) approximate chromaticity or M-to-G and Y-to-B channels (the XZ in XYZ)



A Comparison of Color Spaces

Example RGB Color Space



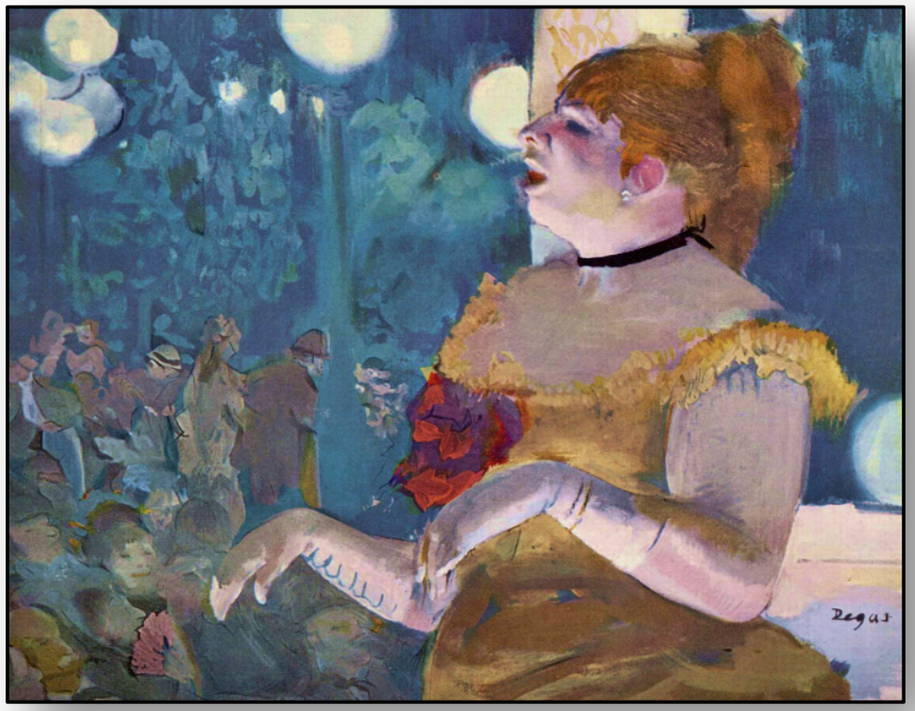
Source

Red

Green

Blue

Example CMY Color Space



Source	Cyan
Magenta	Yellow

Example HSV Color Space

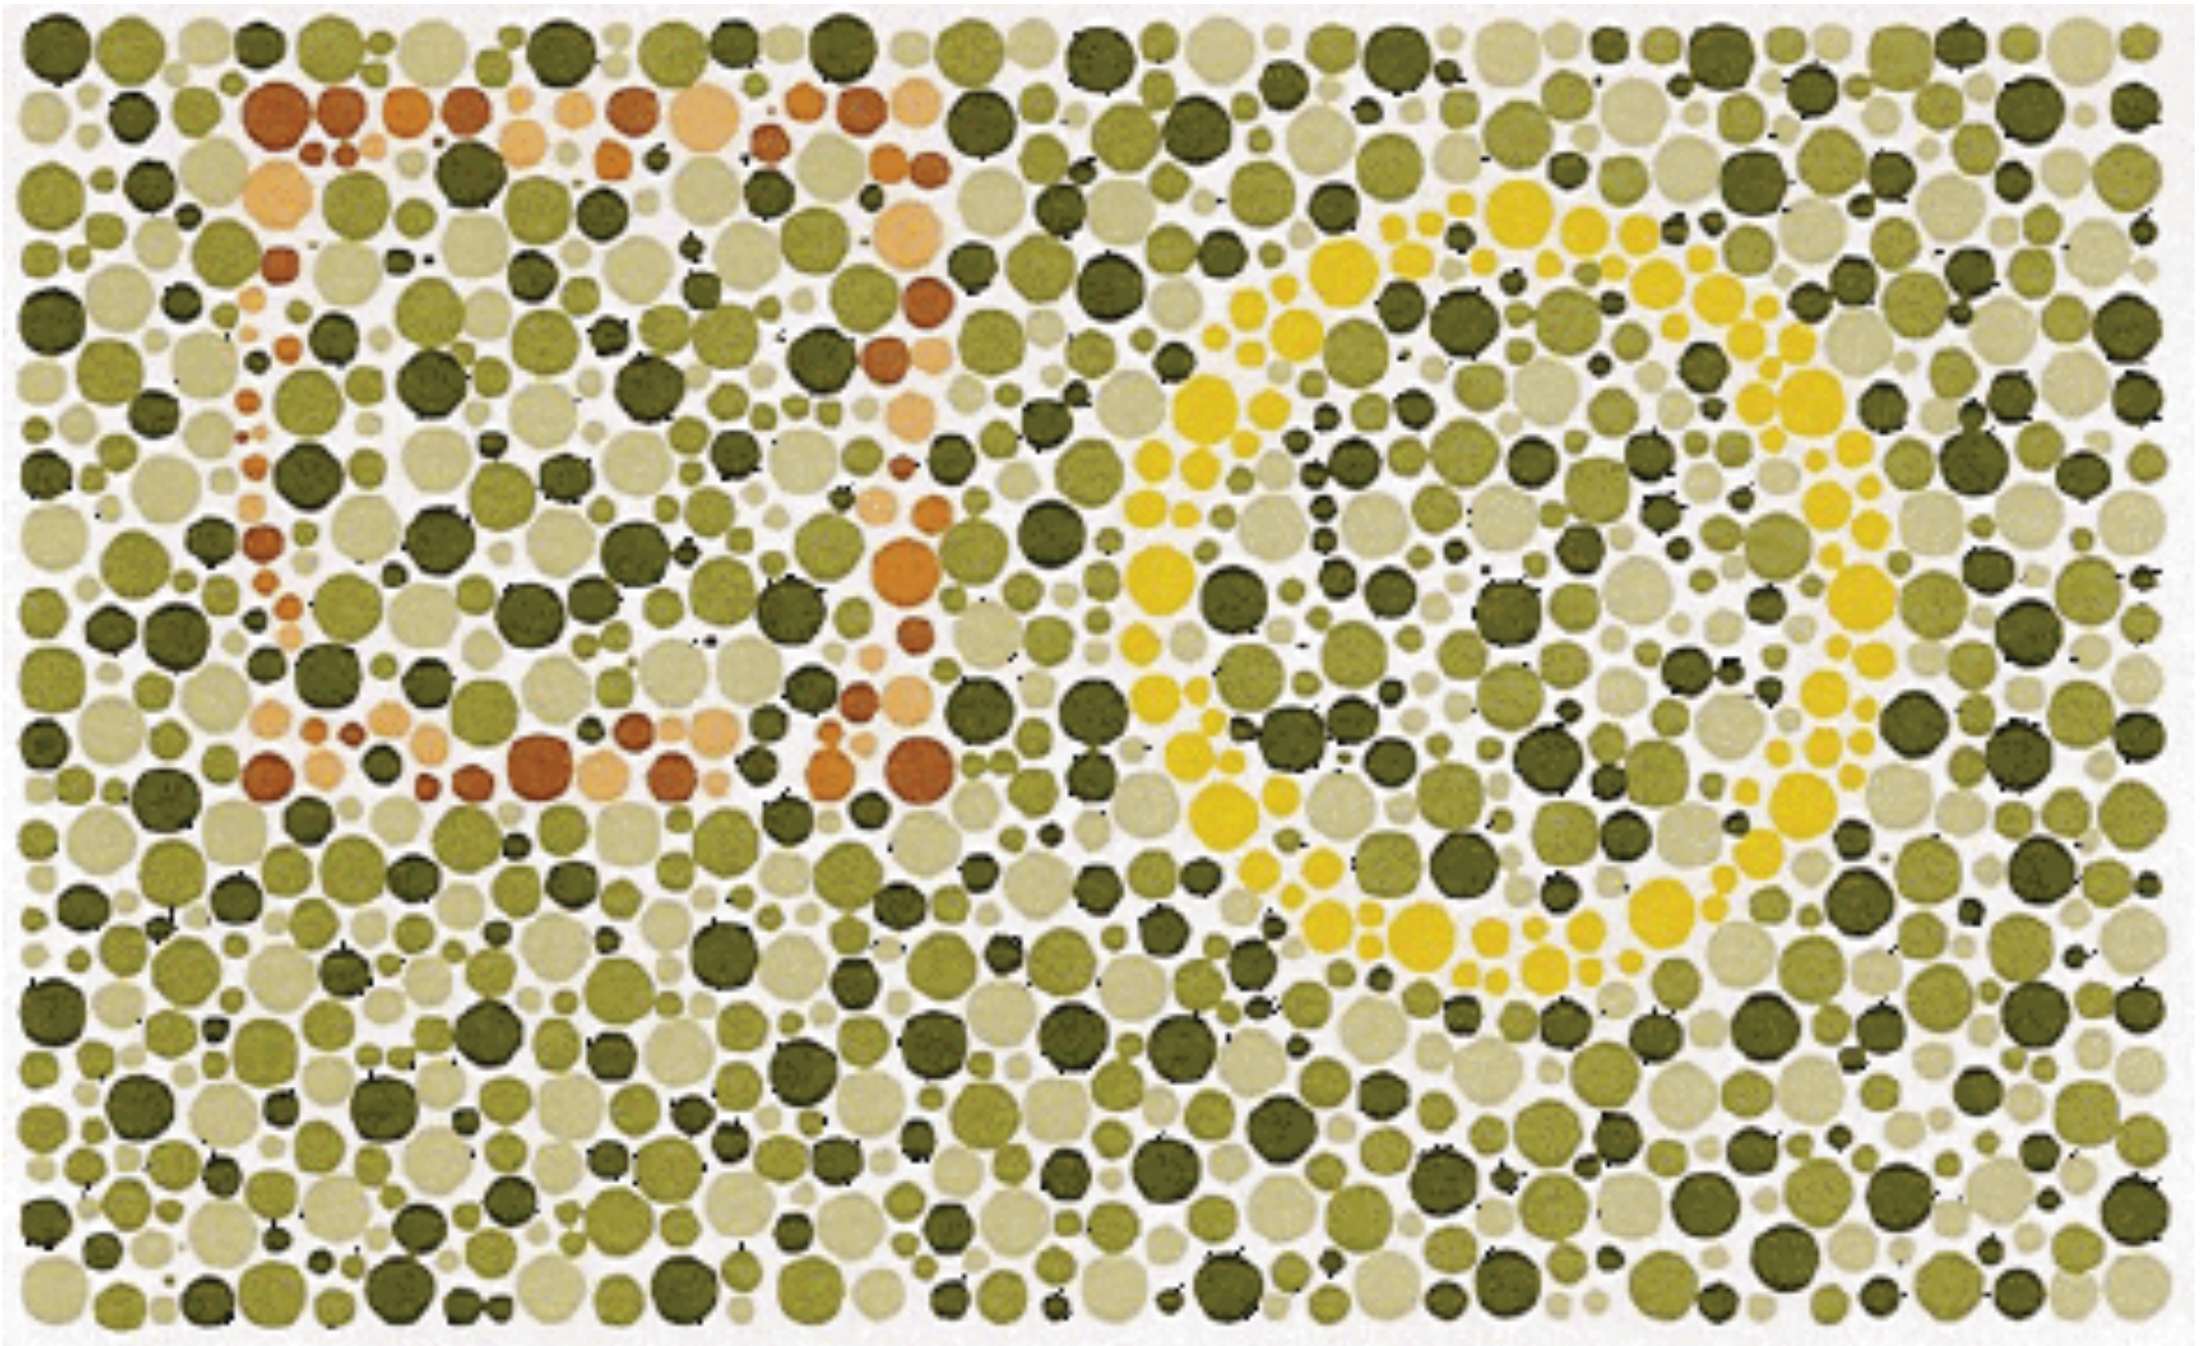
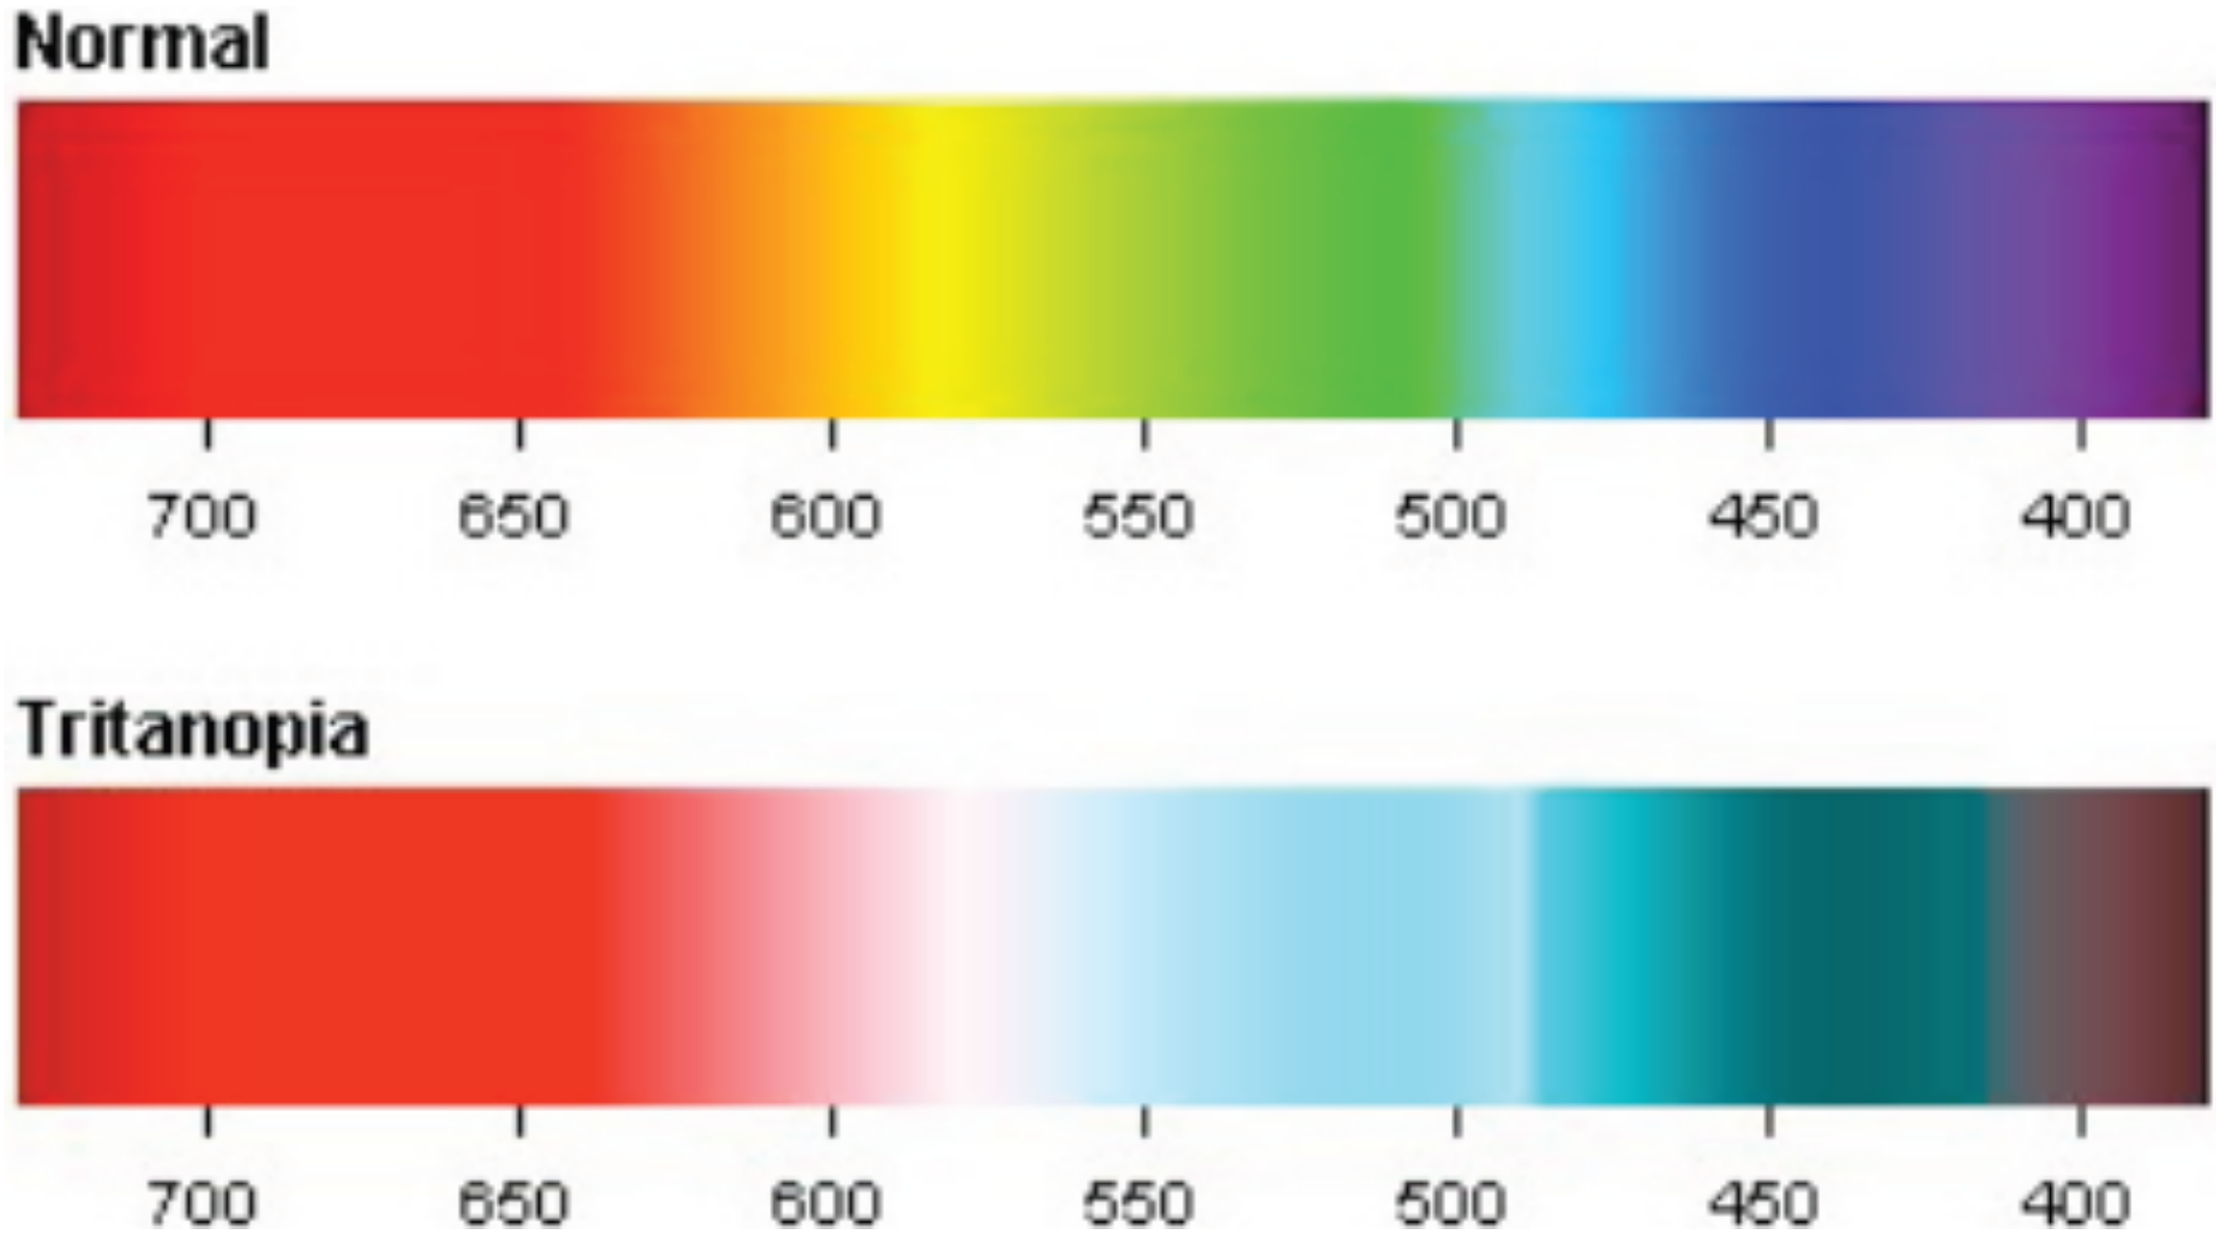
Understanding Color Perception

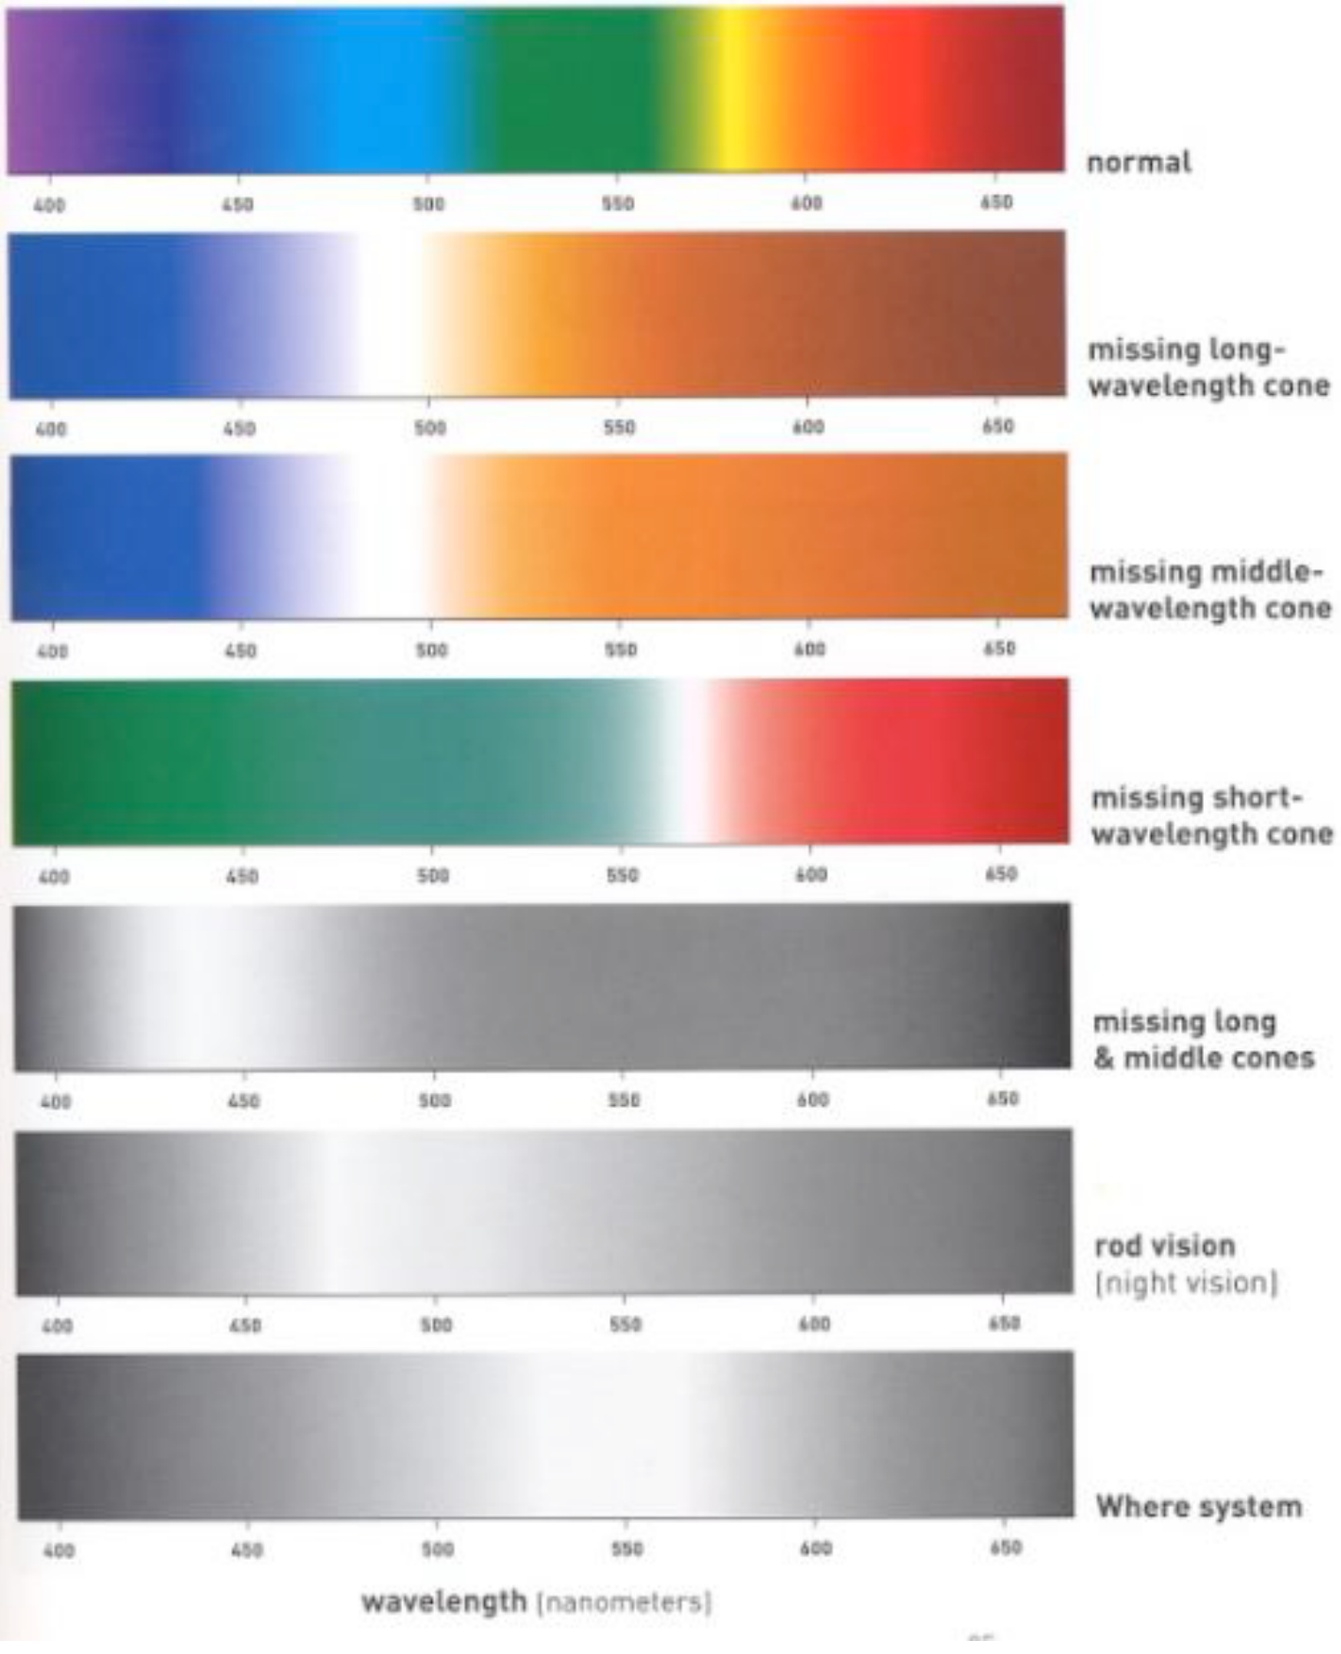
RG Color Blindness

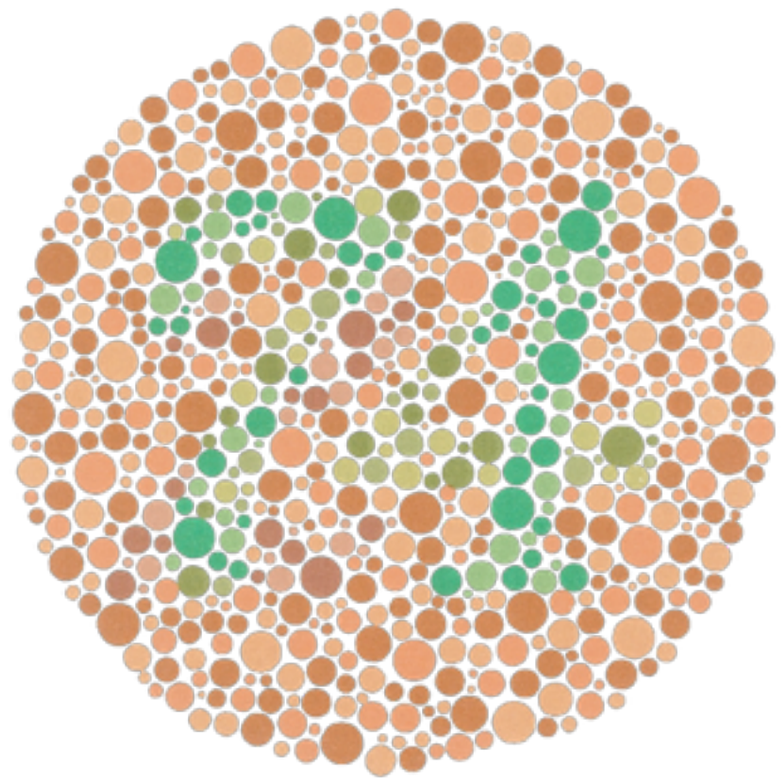


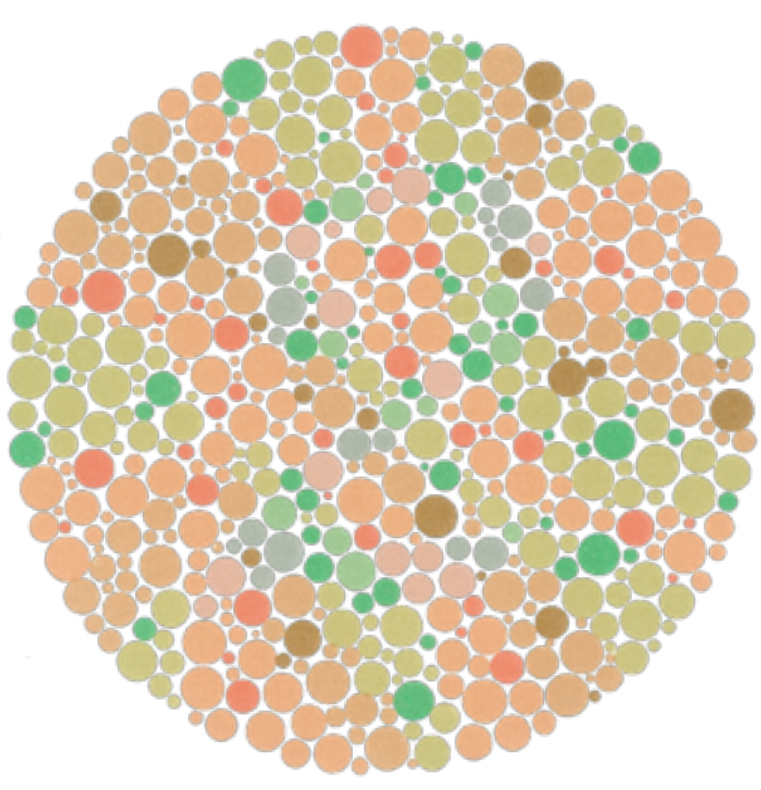
BY Color Blindness



THE DIFFERENT APPEARANCES OF THE VISIBLE SPECTRUM

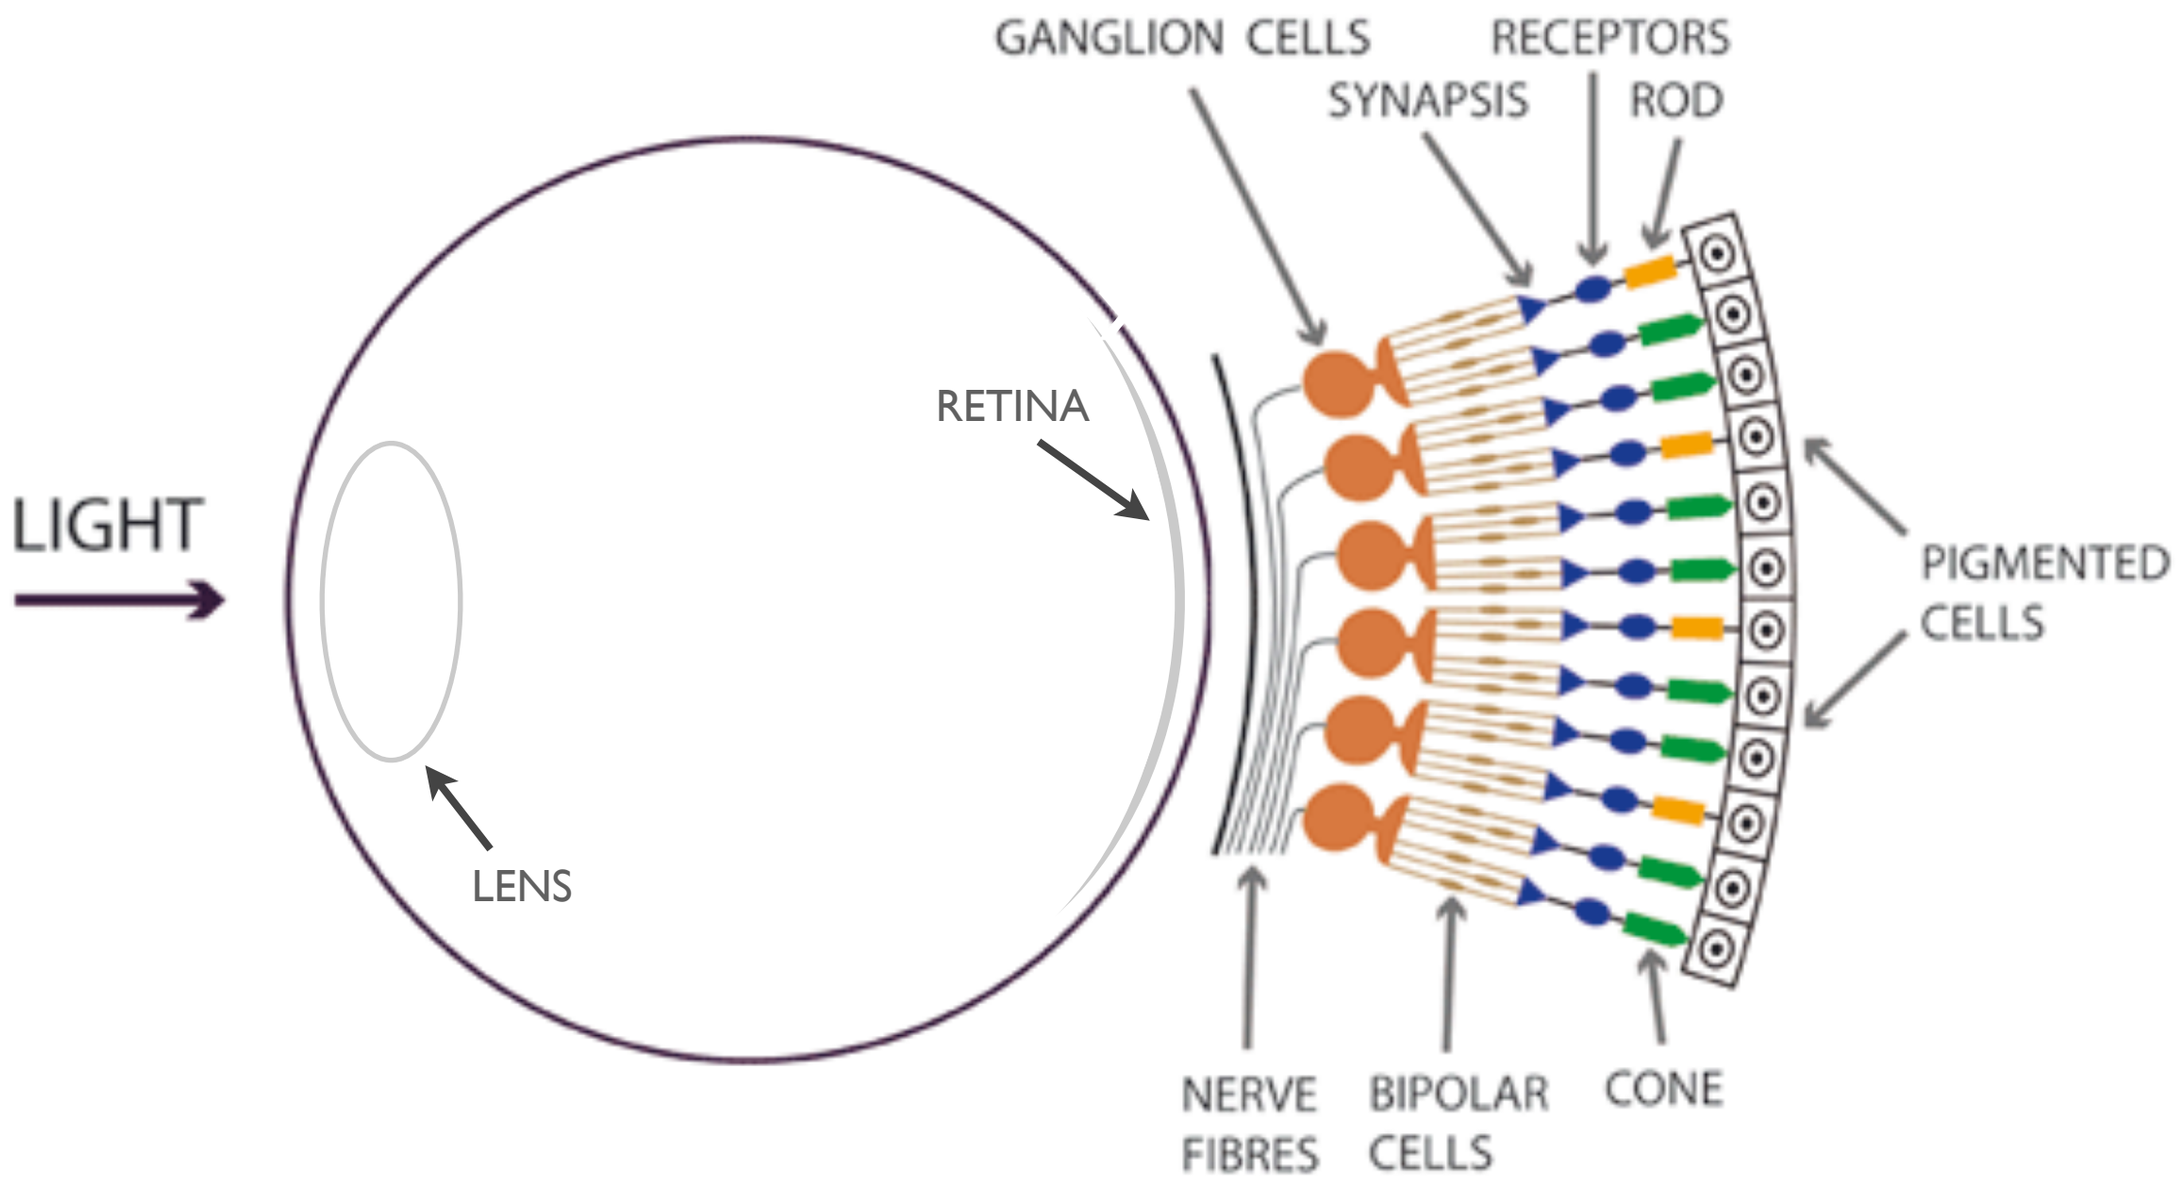






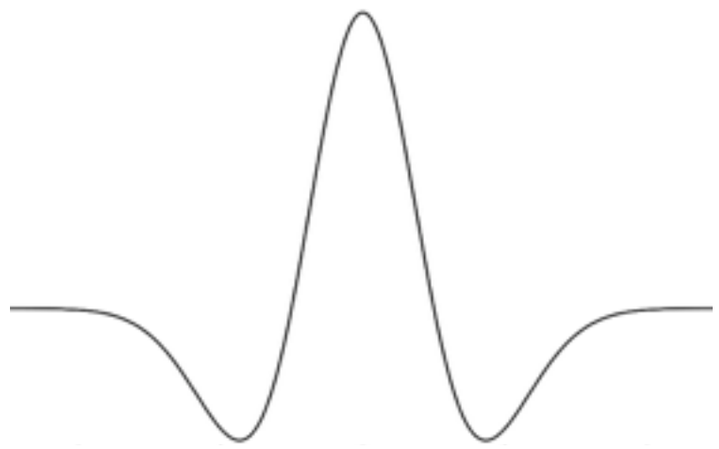
Color Illusions

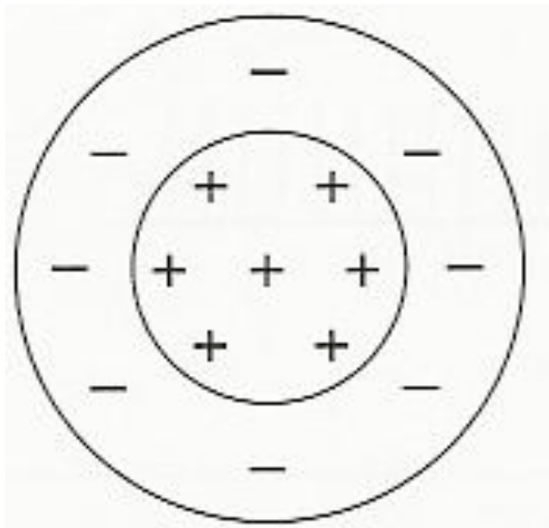
Physiology of the Eye



Color Illusions

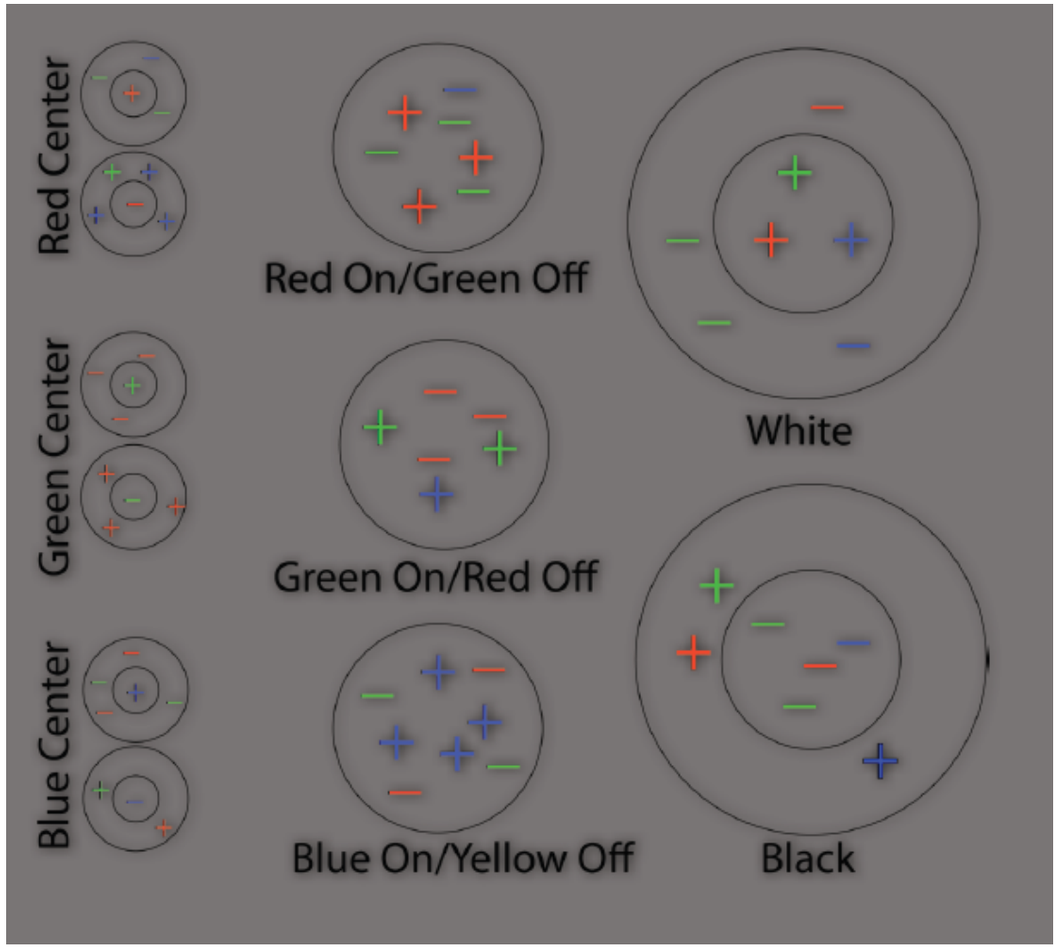
- Primary cause: the Retinal Ganglion Response

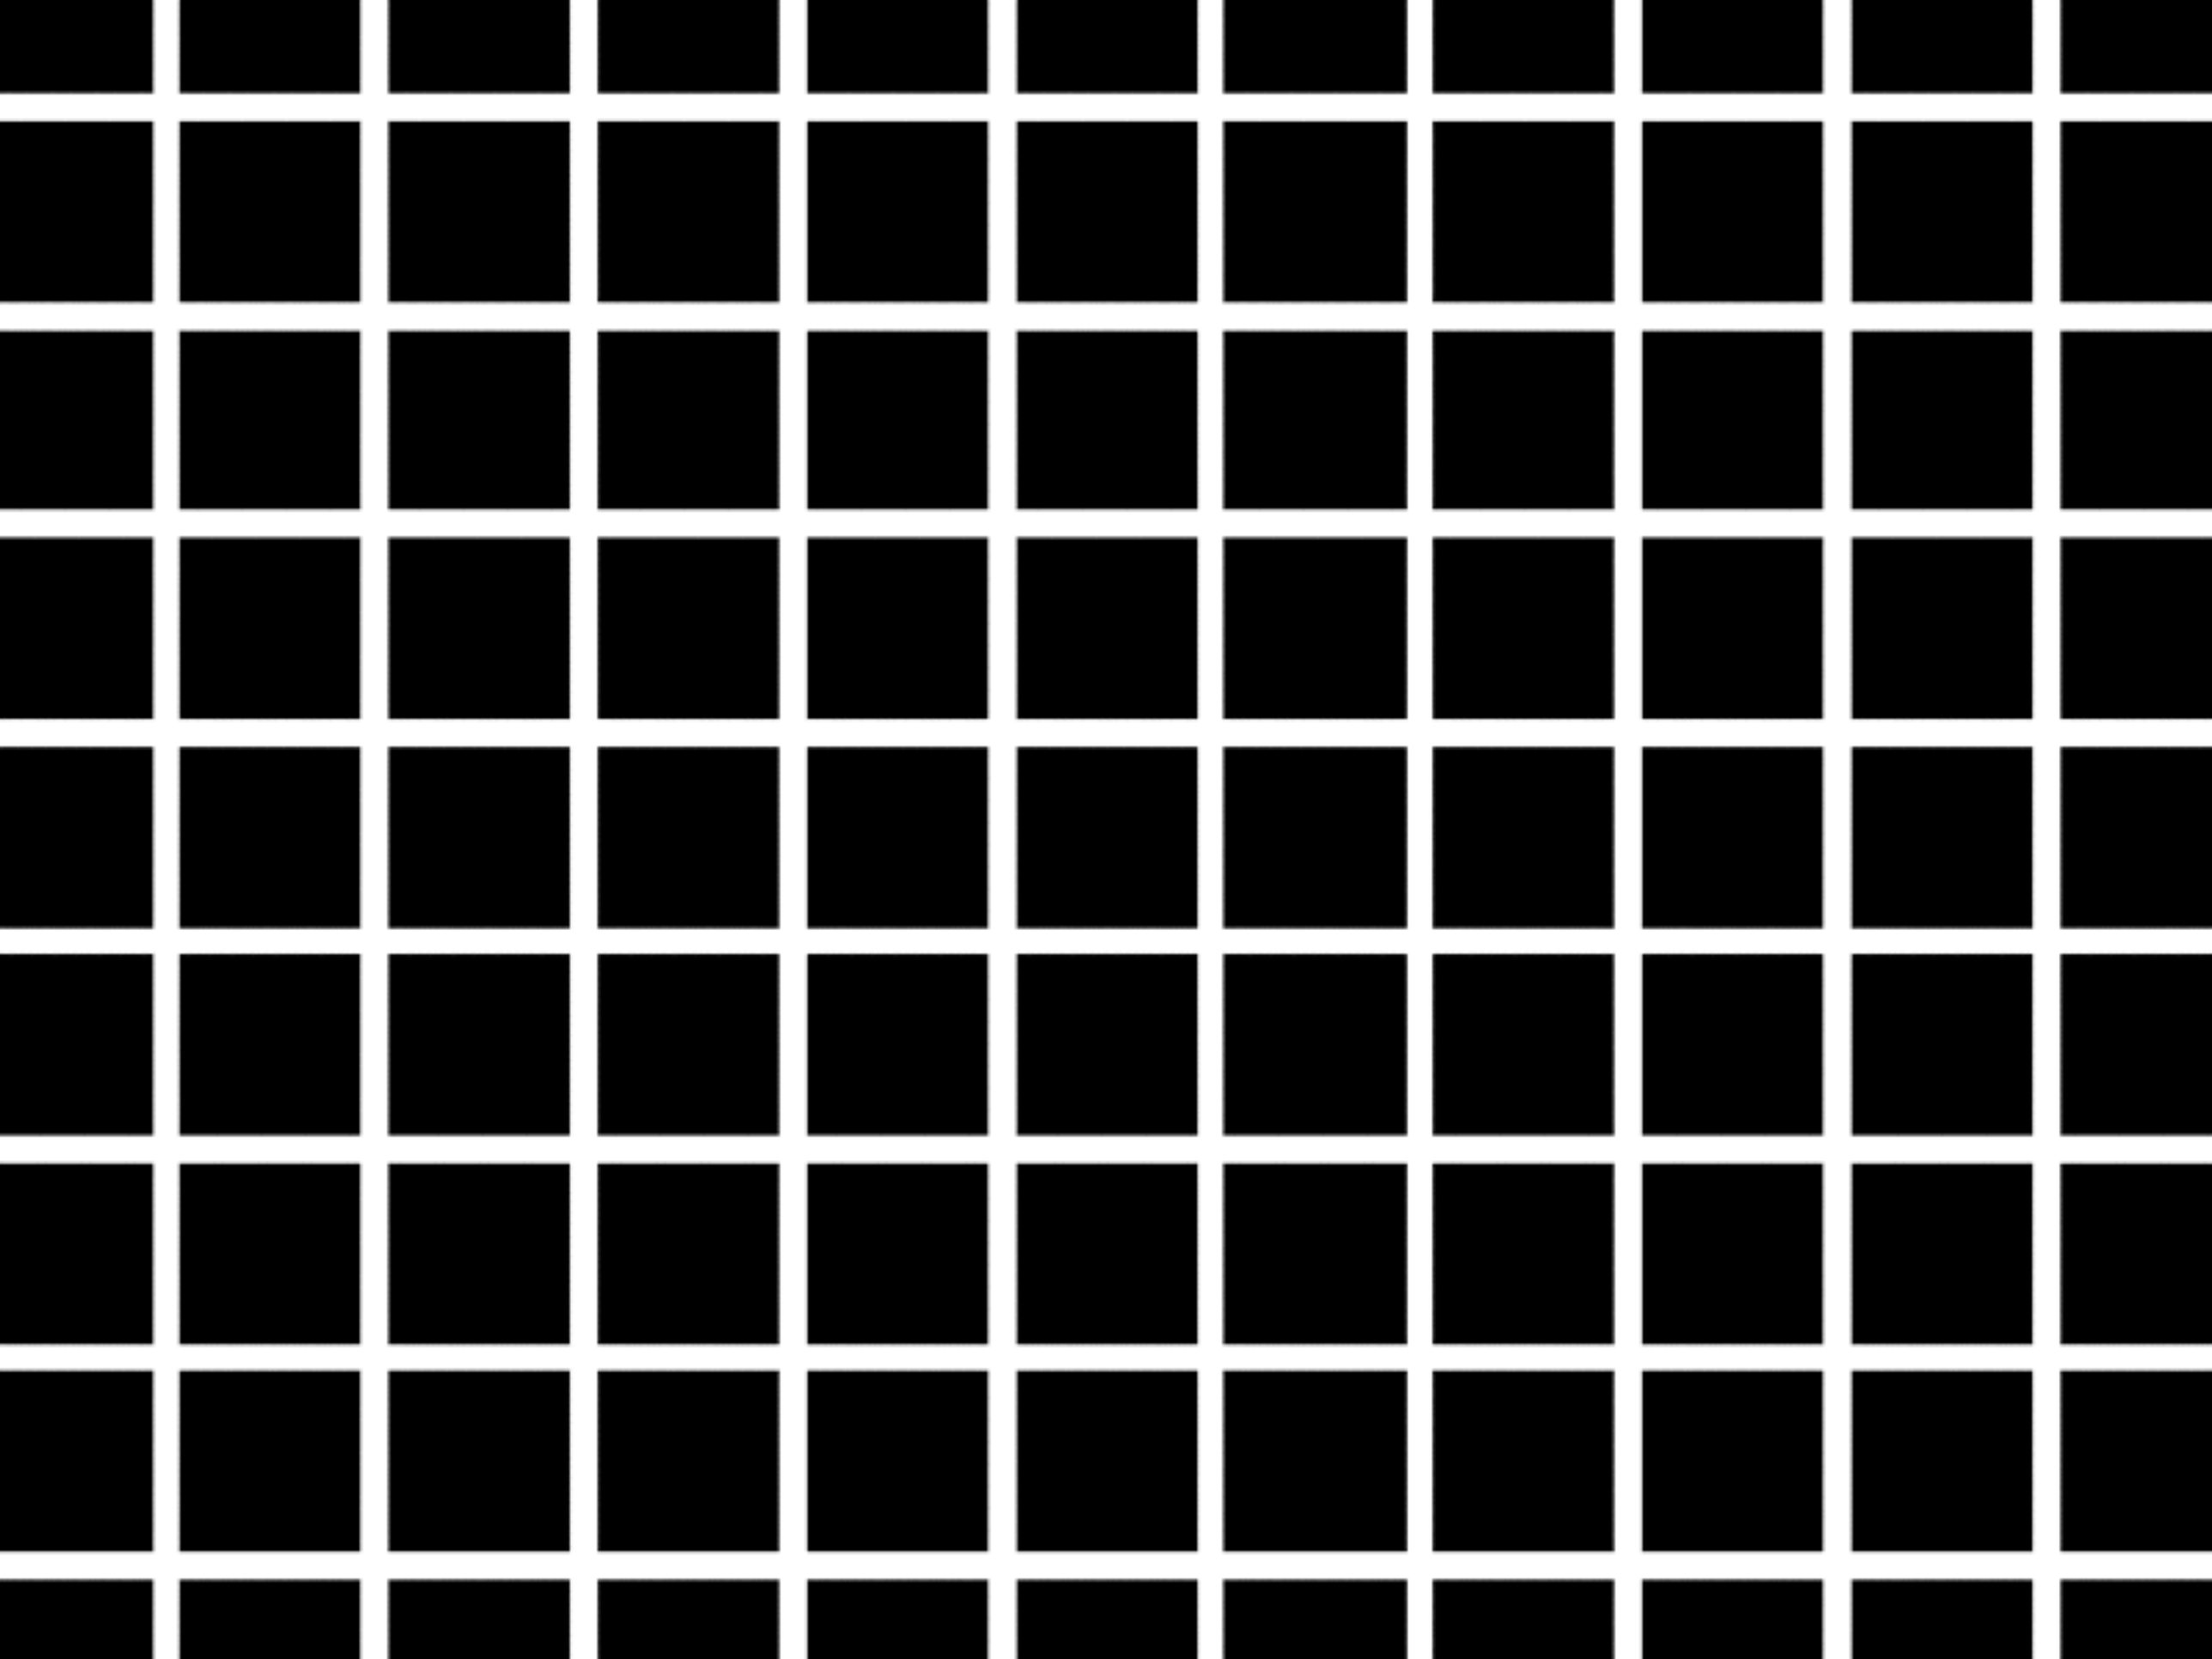




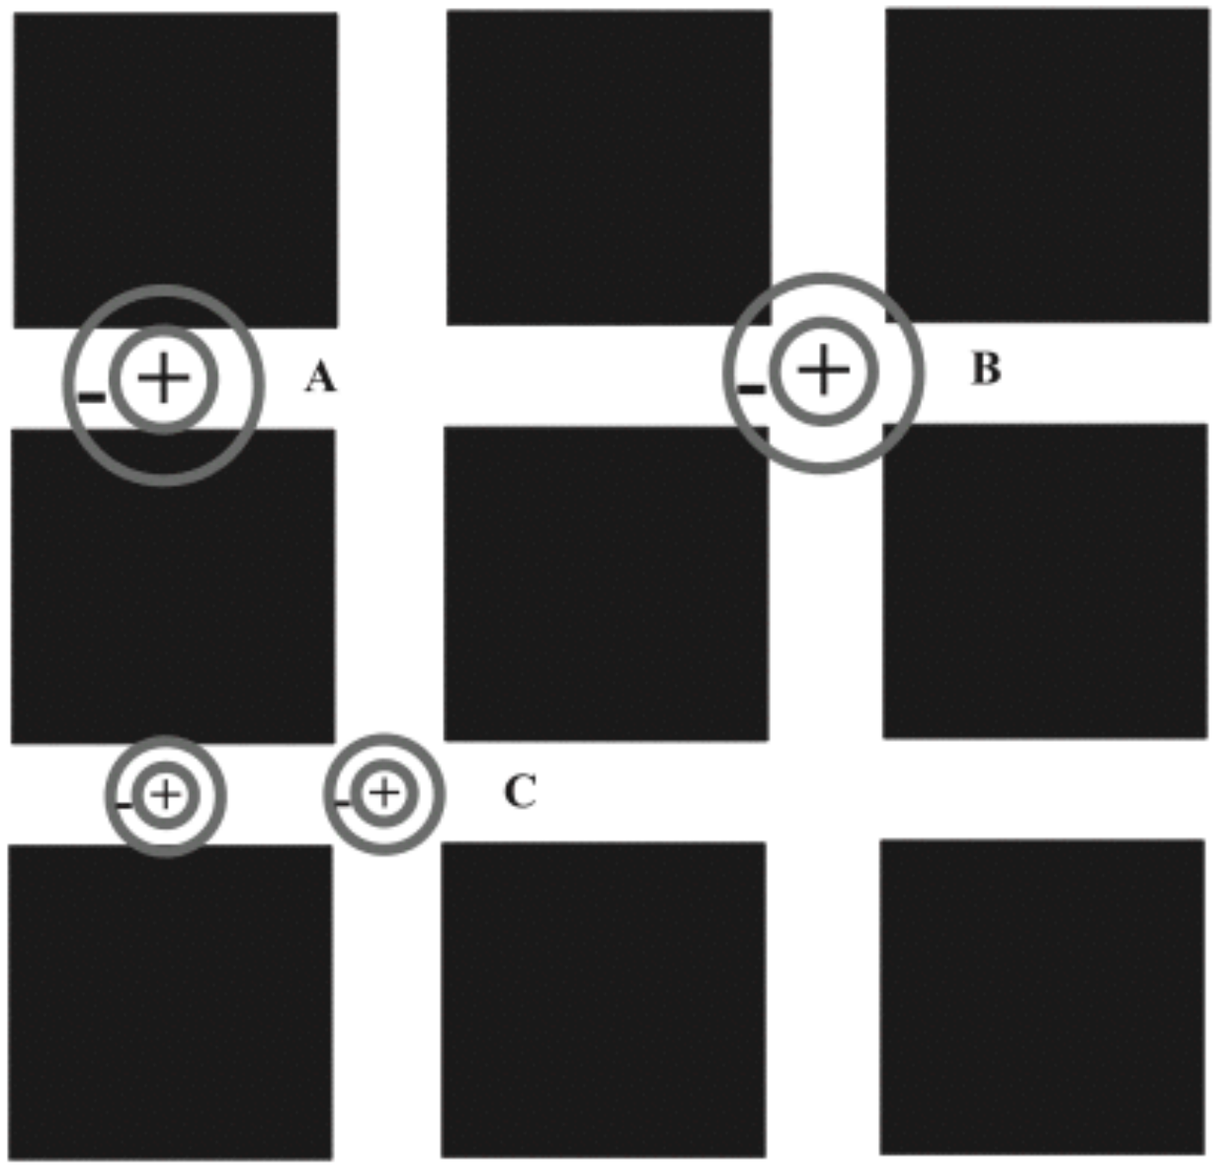
- Triggered by light in the center, suppressed by light in the surround

- Causes selective sensitivities to discontinuities in color as well.





Hermann grid effect (Brightness Adaptation)



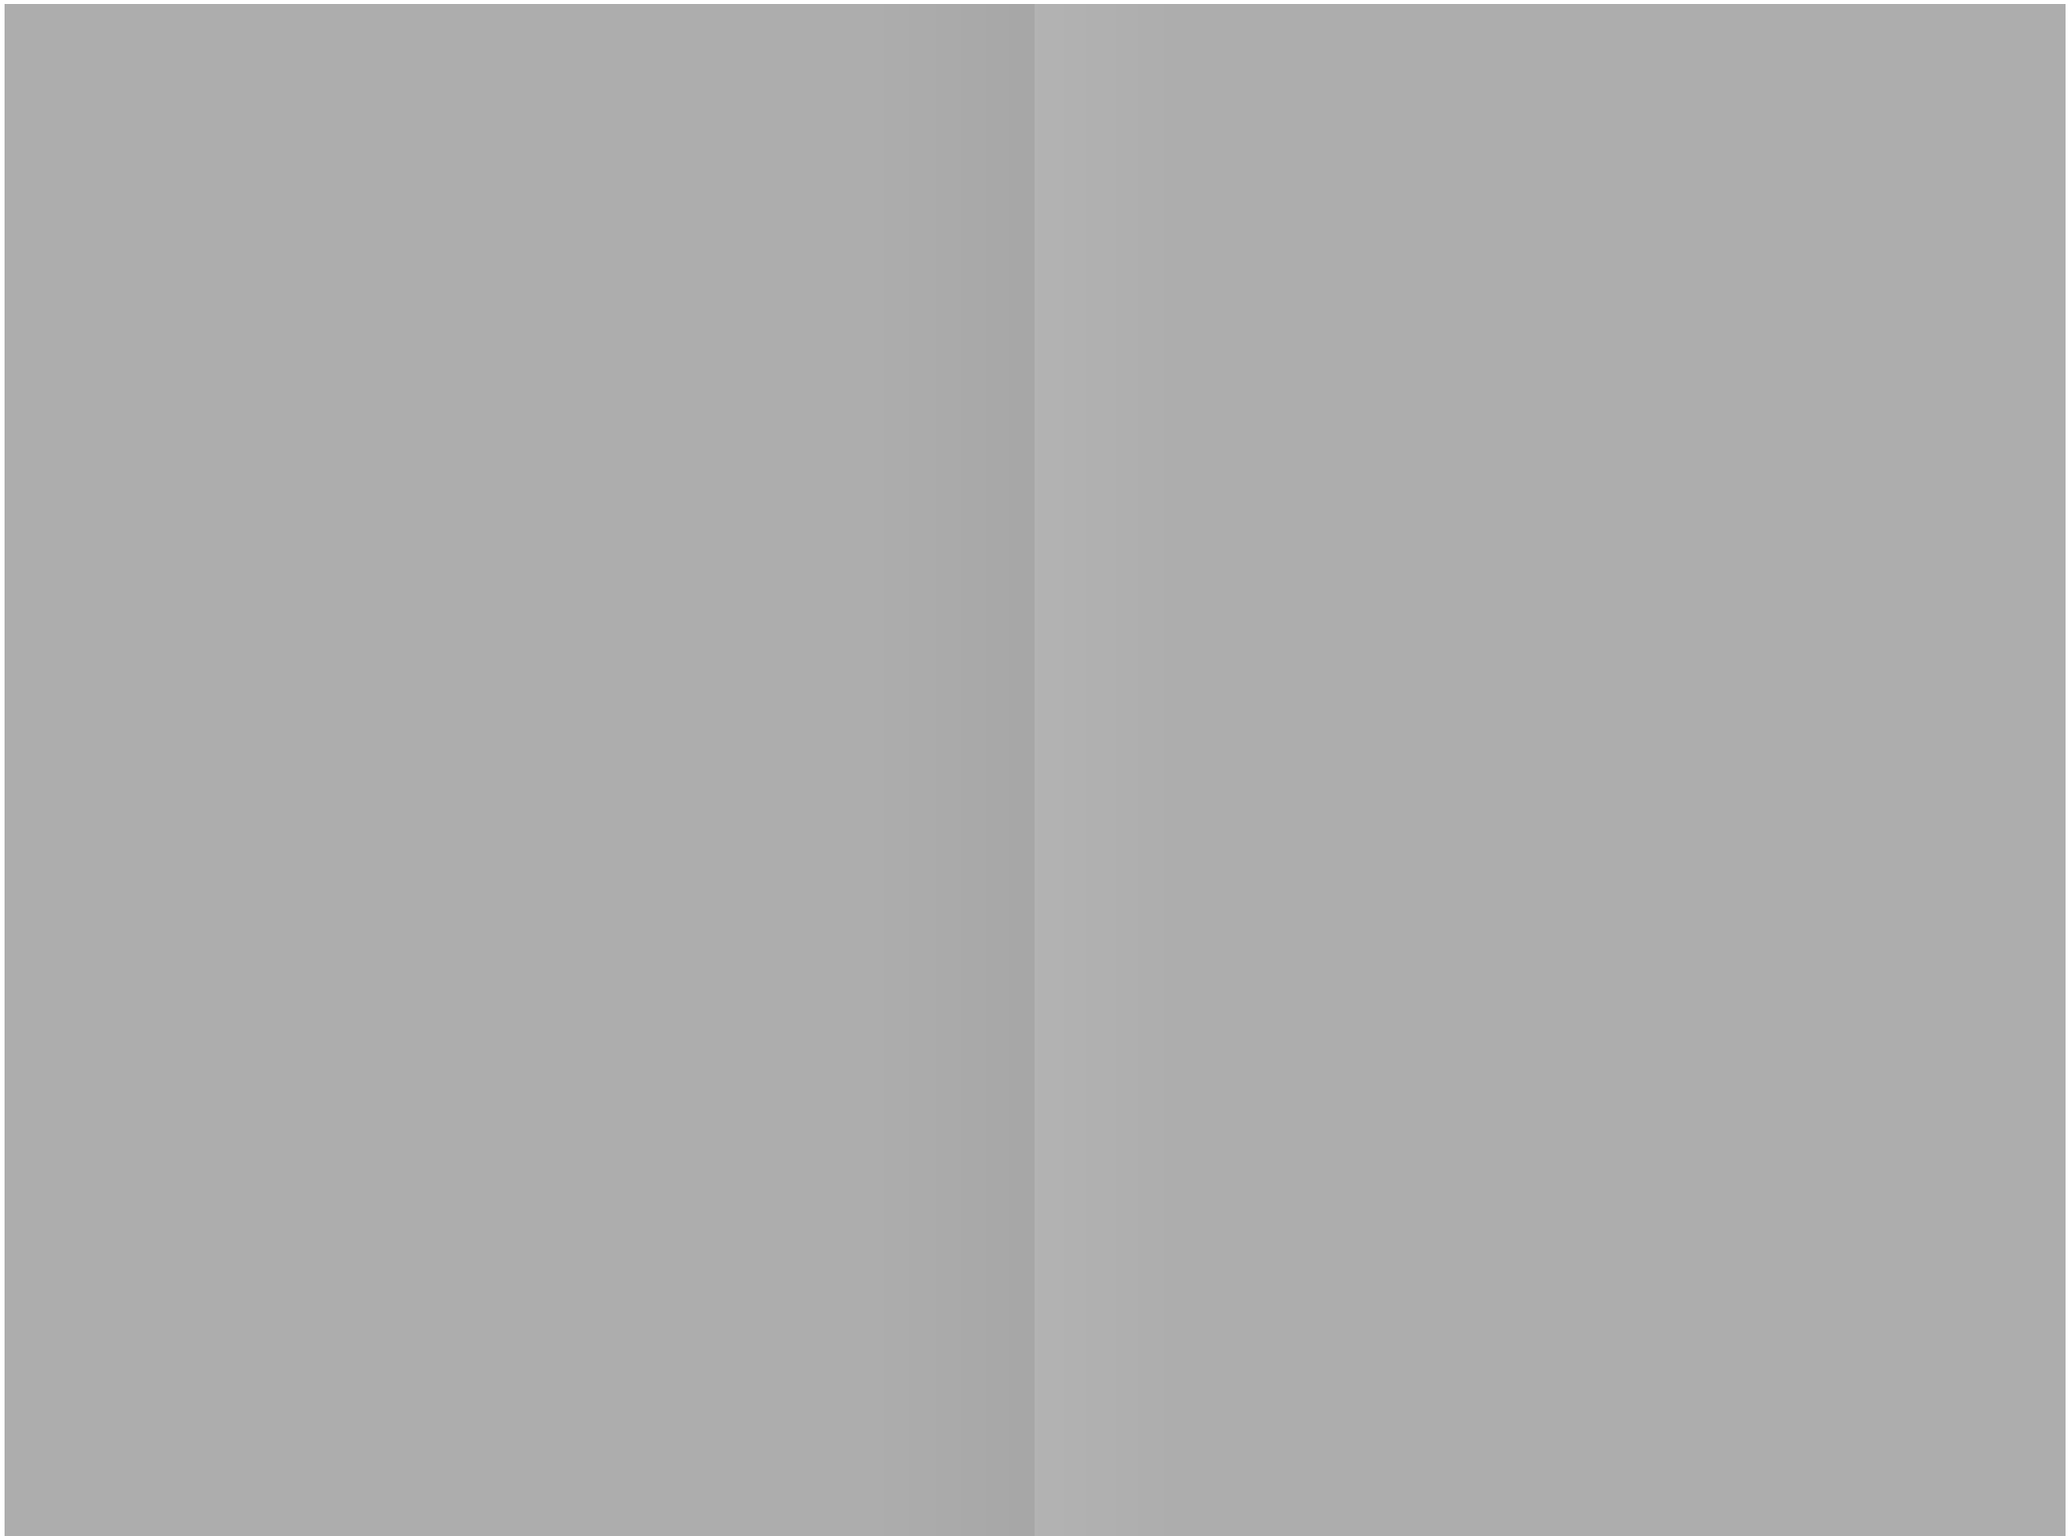
Mach Banding

(a) Mach banding. (b) Row profile of perceived brightness.

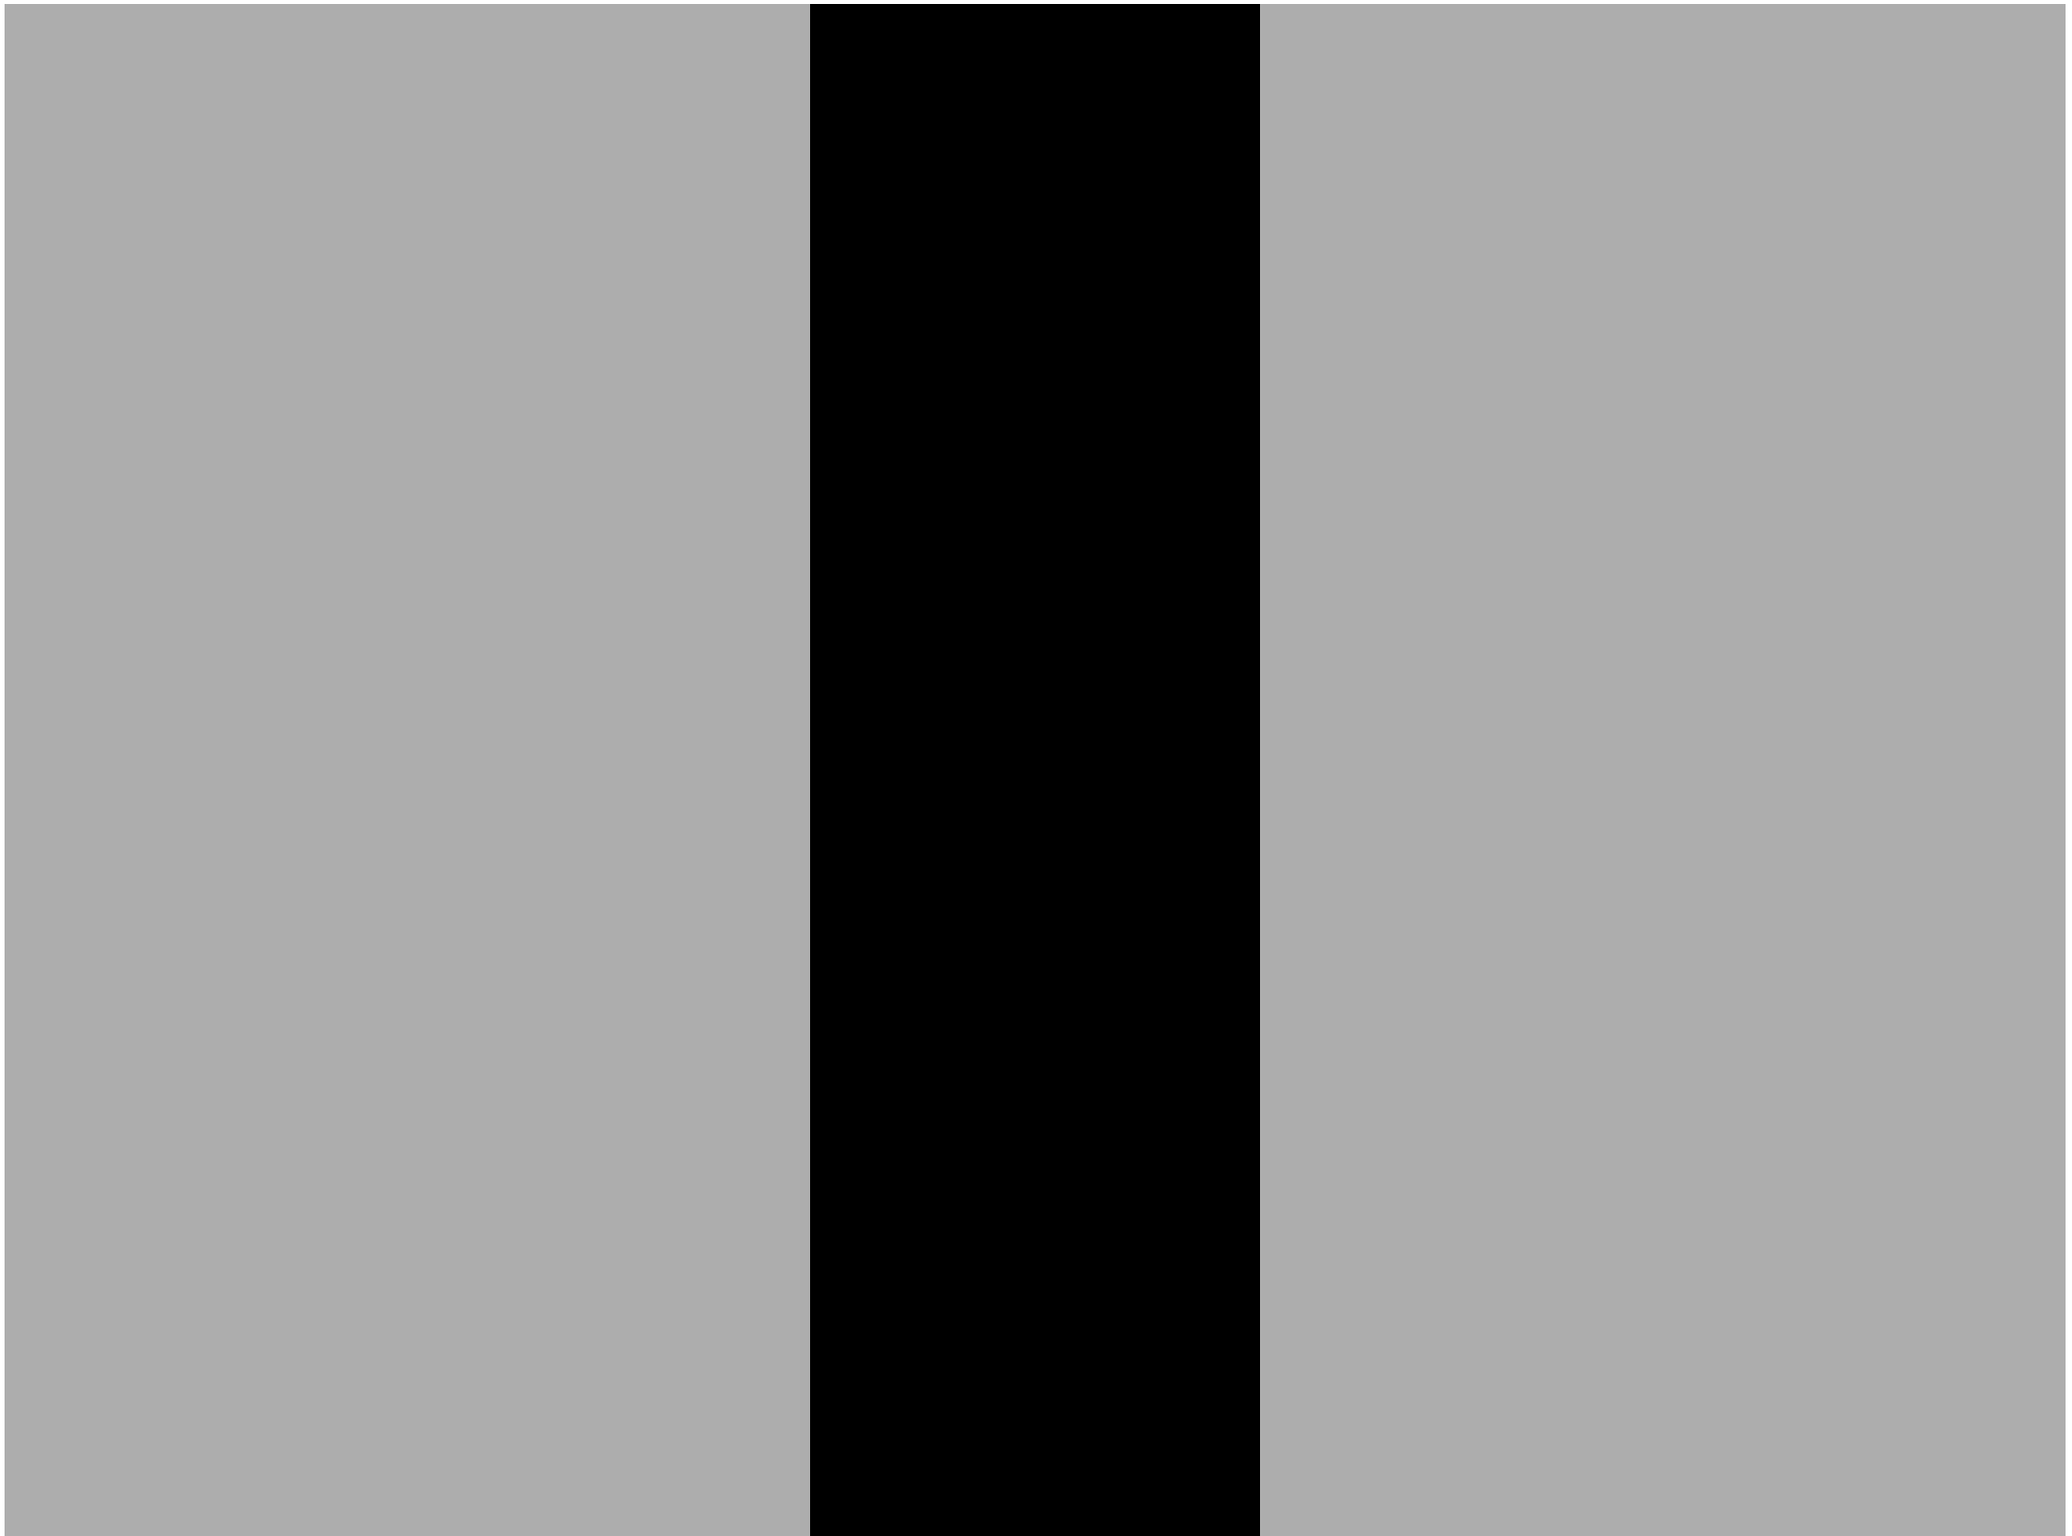
Figure 2.8. Mach banding effect.

- The eye rapidly scans across the field of view while coming to momentary rest at each point of particular interest.
- At each of these points the eye adapts to the average brightness of the local region surrounding the point of interest.
- This phenomena is another type of (local) brightness adaptation.
- The eye over-shoots/under-shoots at edges where the brightness changes rapidly. This causes ‘false perception’ of the intensities

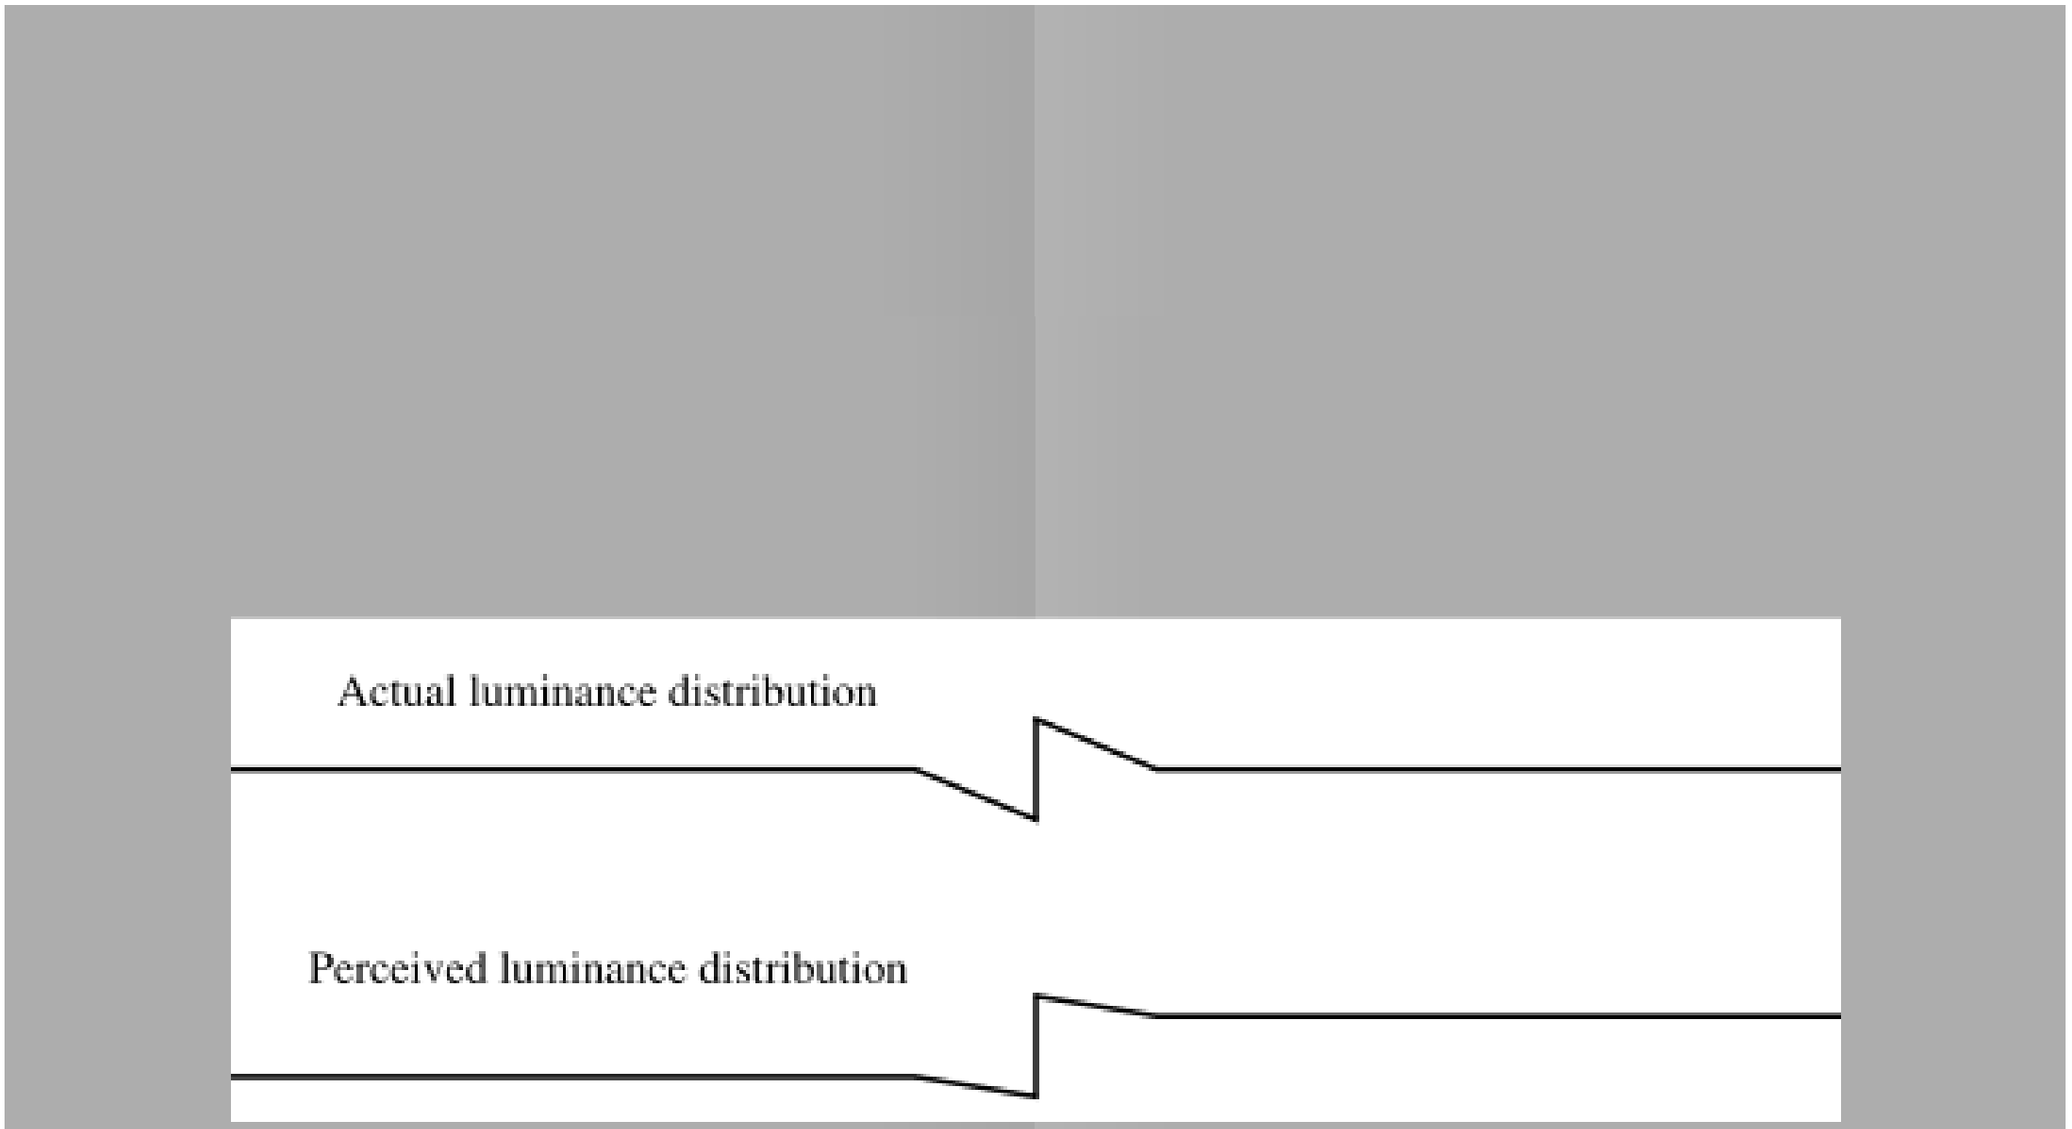
Cornsweet Illusion



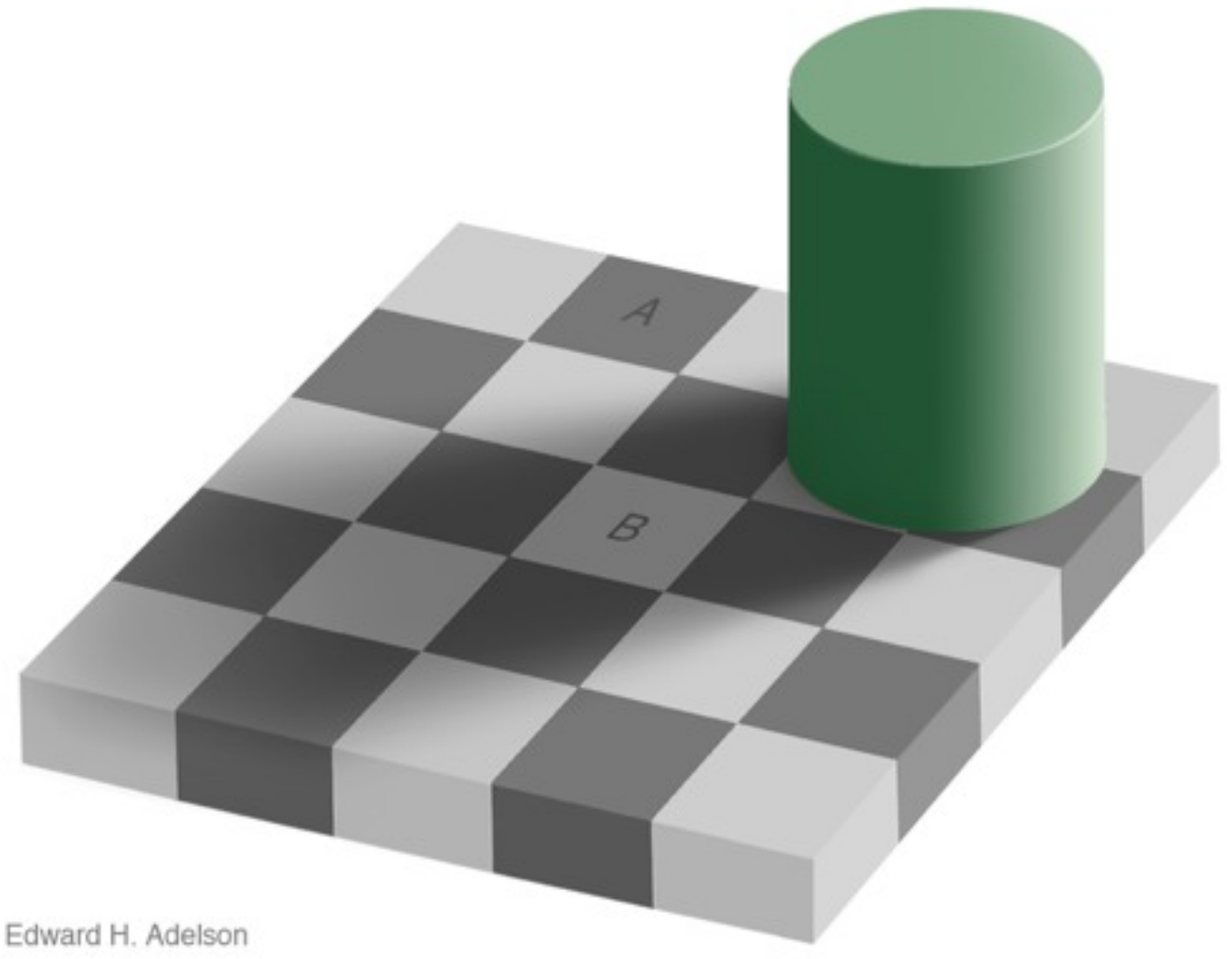
Cornsweet Illusion



Cornsweet Illusion



Simultaneous Contrast



Edward H. Adelson

- Perceived color is highly context dependent
- Variable lighting and background conditions affect what we see.
